Abstract

We investigate the one-dimensional strongly correlated electron models which have the resonating-valence-bond state as the exact ground state. The correlation functions are evaluated exactly using the transfer matrix method for the geometric representations of the valence-bond states. In this method, we only treat matrices with small dimensions. This enables us to give analytical results. It is shown that the correlation functions decay exponentially with distance. The result suggests that there is a finite excitation gap, and that the ground state is insulating. Since the corresponding non-interacting systems may be insulating or metallic, we can say that the gap originates from strong correlation. The persistent currents of the present models are also investigated and found to be exactly vanishing.

I. INTRODUCTION

Strongly interacting electron systems have been always one of the most important subjects in condensed matter physics. Although rigorous results and exact solutions are useful, they are rare. Recently, Brandt and Giesekeus [1] introduced model of strongly interacting electrons on d -dimensional ($d \geq 2$) perovskite-like lattices in which the exact ground-state wave functions were obtained for a certain range of the parameters. Mielke [2] showed that the exact ground state can be obtained in similar models on a general class of line graphs. Following the line of Brandt and Giesekeus, models in which the exact ground state can be obtained were constructed by several authors [3,4,5]. These models are conveniently described by the cell construction of Tasaki [4] which will be reviewed in Sec. II (also see Appendix A and Ref. [5]). Tasaki [5] proved the uniqueness of the ground states in this class of models. Not only the ground state but also the singlet-pair correlation function in a model on a tree was obtained [4]. Bares and Lee [6] performed a detailed analysis for one of the models of Strack [3]. They proved the uniqueness of the ground state and exactly evaluated the equal-time correlation functions by a transfer matrix method.

It was pointed out [4,6] that the exact ground states have the resonating-valence-bond (RVB) structure [7,8]. It is the so-called hopping-dominated RVB states [9] which is different from the tunneling-dominated RVB states. The latter have been studied intensively in connection to the high T_c superconductivity [10,11,12,13,14,15,16]. Tasaki and Kohmoto [9] studied the difference of the mechanism that causes the resonance in the hopping-dominated RVB states and the tunneling-dominated RVB states.

In this paper we shall exactly evaluate the equal-time correlation functions of one-dimensional models (Model A, B, and C) which will be defined in Sec. IV. One of the models of Strack which was studied by Bares and Lee is called Model B in this paper. We shall use the transfer matrix method for the geometric representations of the valence-bond states [13,16,17,18], which is different from that of Bares and Lee. In one dimension, the extension of the formalism to other models which will not be included in this paper is cumbersome but essentially straightforward. It is crucial that we do not have to treat large matrices as needed in the method of Bares and Lee. (In one of the models by Strack, for example, we only treat 3×3 transfer matrices, while Bares and Lee needed those of 16×16 .) This enables us to give the completely analytical solution with finite amount of efforts.

It is shown that all the correlation functions decay exponentially with distance. The result suggests that the existence of a finite excitation gap. It is expected that the excitation gap is originated from the structure of the ground state which is described by a collection of local spin singlets. The filling factor of the ground state corresponds to that of a band insulating state or metallic one in the non-interacting system. The properties of the ground state and the gap are completely different from that in the non-interacting system. The existence of the excitation gap is expected to be a general feature of this class of models. In a certain range of parameters, Model B includes one of the models by Strack [3,6], where we reproduce the results of Bares and Lee. In a limit of parameters, it corresponds to a kind of the Kondo lattice regime in the sense that there are one localized electron and one conduction electron per a unit cell, where the ground state is described by a collection of a local singlet between them. The persistent currents [19,20,21,22,23] are also calculated and turned out to be vanishing.

The plan of this paper is as follows: In Sec. II, we review the cell construction of the models. In Sec. III we describe the geometric representation of the correlation functions in arbitrary dimensions. In Sec. IV, we perform a detailed analysis of the one-dimensional models using the method in Sec. III. In Sec. V, the absence of the persistent currents is shown. Section VI is a summary. The reader who is interested only in the physical results may take a look at Sec. II and VI for general properties of systems in one dimension, and then read Sec. IV A 1, IV A 6, IV C 1, IV C 4, IV D 1, and IV D 4 as examples. The results for the correlation functions are shown in each end of subsubsection in Sec. IV.

II. CELL CONSTRUCTION AND THE GROUND STATE

Let us first introduce the solvable models in arbitrary dimension by following the construction in Refs. [4] and [5]. In the present paper, we only consider the translation invariant lattices¹. The lattice is constructed from identical cells C_n with $n = 1, 2, \dots, N$, where N is the number of the cells. The cell C_n is a finite set of sites, where each site $r \in C_n$ ($r = 1, 2, \dots, R$, where² $R = |C_n|$) is either a site with infinitely large on-site Coulomb repulsion (a $U = \infty$ site or a d -site) which can have at most one electron, or a $U = 0$ site (or a p -site) which can have at most two electrons with opposite spins. The full lattice $\Lambda_N (= \cup_{n=1}^N C_n)$ is constructed by starting from the lattice $\Lambda_1 = C_1$, and adding cells $C_2, C_3, \dots, C_N$ successively. When we add a new cell C_{n+1} to the lattice $\Lambda_n (= \cup_{i=1}^n C_i)$, we identify some of sites in C_{n+1} with sites in Λ_n in a one-to-one manner. We note that a cell is not a unit cell in the sense of crystallography. We denote sites in the full lattice Λ_N by x ($x = 1, 2, \dots, |\Lambda_N|$). A site x may belong to several different cells. The correspondence between x ($\in \Lambda_N$) and r ($\in C_n$) is given by

$$x = f(n, r), \quad (2.1)$$

where $f(n, r)$ depends on the model under consideration. See Fig. 1 for the correspondence.

For a cell C_n , we associate a cell Hamiltonian

$$H_n = \sum_{\sigma=\uparrow, \downarrow} \alpha_{n,\sigma} \mathcal{P}_n \alpha_{n,\sigma}^\dagger, \quad (2.2)$$

with

$$\alpha_{n,\sigma} = \sum_{r=1}^R \lambda_r^{(n)} c_{r,\sigma}, \quad (2.3)$$

where $\lambda_r^{(n)}$ are nonvanishing complex coefficients³ and are chosen independently in each cell⁴. (In Sec. V, we can impose the twisted boundary condition by making use of this property. In Secs. III and IV, we only consider cases where all the cells have the same λ_r . Thus we have translationally invariant systems and we drop the suffix n in $\lambda_r^{(n)}$ there.) Here $c_{r,\sigma}$ and $c_{r,\sigma}^\dagger$ are the annihilation and the creation operators, respectively, of an electron at site r with spin $\sigma = \uparrow, \downarrow$. They satisfy the standard anticommutation relations $\{c_{r,\sigma}^\dagger, c_{s,\tau}\} = \delta_{r,s} \delta_{\sigma,\tau}$ and $\{c_{r,\sigma}^\dagger, c_{s,\tau}^\dagger\} = \{c_{r,\sigma}, c_{s,\tau}\} = 0$. The projection operator which eliminates a double occupancy on d -sites is

$$\mathcal{P}_n = \prod_{r \in C_n; U=\infty} (1 - n_{r,\uparrow} n_{r,\downarrow}), \quad (2.4)$$

where $C_n; U=\infty$ is the set of $U = \infty$ sites in C_n and $n_{r,\sigma} = c_{r,\sigma}^\dagger c_{r,\sigma}$ is the number operator. This represents the infinitely large on-site Coulomb repulsion. The full Hamiltonian is

¹We can construct more generalized models whose lattices are not translation invariant. See Ref. [5] for such models.

²Throughout the present paper, $|S|$ denotes the number of elements in a set S .

³When a magnetic field is applied, $\lambda_r^{(n)}$ are complex. The proof of the uniqueness of the ground state in Ref. [5] holds also in this case.

⁴When a site x belongs to more than one cells, $\lambda_x^{(n)}$ can be chosen independently in each cell.

$$H = \sum_{n=1}^N H_n. \quad (2.5)$$

We rewrite this Hamiltonian into the “standard form”. From the identities [1,5]

$$\begin{aligned} c_{r,\sigma} \mathcal{P}_n c_{s,\sigma}^\dagger &= -\mathcal{P}_n c_{s,\sigma}^\dagger c_{r,\sigma} \mathcal{P}_n & \text{for } r \neq s \\ c_{r,\sigma} \mathcal{P}_n c_{r,\sigma}^\dagger &= \mathcal{P}_n (1 - n_{r,\uparrow} - n_{r,\downarrow}) \mathcal{P}_n & \text{for } r \in C_{n;U=\infty} \\ c_{r,\sigma} \mathcal{P}_n c_{r,\sigma}^\dagger &= \mathcal{P}_n (1 - n_{r,\sigma}) \mathcal{P}_n & \text{for } r \in C_{n;U=0}, \end{aligned} \quad (2.6)$$

where $C_{n;U=0}$ is the set of $U=0$ sites in C_n , the cell Hamiltonian (2.2) is

$$\begin{aligned} H_n &= \sum_{\sigma=\uparrow,\downarrow} \sum_{r,s \in C_n} \lambda_s^{(n)} \left(\lambda_r^{(n)} \right)^* c_{s,\sigma} \mathcal{P}_n c_{r,\sigma}^\dagger \\ &= \mathcal{P}_n \left\{ \sum_{r \in C_n} 2 \left| \lambda_r^{(n)} \right|^2 - \left[\sum_{\sigma=\uparrow,\downarrow} \sum_{r \neq s (\in C_n)} \left(\lambda_r^{(n)} \right)^* \lambda_s^{(n)} c_{r,\sigma}^\dagger c_{s,\sigma} \right. \right. \\ &\quad \left. \left. + \sum_{\sigma=\uparrow,\downarrow} \sum_{r \in C_{n;U=\infty}} 2 \left| \lambda_r^{(n)} \right|^2 c_{r,\sigma}^\dagger c_{r,\sigma} + \sum_{\sigma=\uparrow,\downarrow} \sum_{r \in C_{n;U=0}} \left| \lambda_r^{(n)} \right|^2 c_{r,\sigma}^\dagger c_{r,\sigma} \right] \right\} \mathcal{P}_n \\ &= \mathcal{P}_n \left\{ E_n - \sum_{\sigma=\uparrow,\downarrow} \sum_{r,s \in C_n} t_{r,s}^{(n)} c_{r,\sigma}^\dagger c_{s,\sigma} \right\} \mathcal{P}_n, \end{aligned} \quad (2.7)$$

where

$$t_{r,s}^{(n)} = \begin{cases} \left(\lambda_r^{(n)} \right)^* \lambda_s^{(n)} & \text{for } r \neq s \\ 2 \left| \lambda_r^{(n)} \right|^2 & \text{for } r = s \text{ and } r, s \in C_{n;U=\infty} \\ \left| \lambda_r^{(n)} \right|^2 & \text{for } r = s \text{ and } r, s \in C_{n;U=0} \end{cases} \quad (2.8)$$

$$E_n = \sum_{r \in C_n} 2 \left| \lambda_r^{(n)} \right|^2. \quad (2.9)$$

From (2.5), we have

$$H = -E_0 - \mathcal{P} \sum_{\sigma=\uparrow,\downarrow} \sum_{x,y \in \Lambda_N} t_{x,y} c_{x,\sigma}^\dagger c_{y,\sigma} \mathcal{P}, \quad (2.10)$$

where

$$t_{x,y} = \sum_{n=1}^N t_{r,s}^{(n)} \quad \text{for } x = f(n, r), y = f(n, s) \quad (2.11)$$

$$E_0 = - \sum_{n=1}^N E_n, \quad (2.12)$$

and

$$\mathcal{P} = \prod_{n=1}^N \mathcal{P}_n. \quad (2.13)$$

It was shown in Refs. [4,5] that for the electron number, $2N$, the unique ground state of the Hamiltonian (2.5) or (2.10) has zero energy and is given by

$$\left| \Phi_{G.S.} \right\rangle = \mathcal{P} \prod_{\sigma=\uparrow,\downarrow} \prod_{n=1}^N \alpha_{n,\sigma}^\dagger \left| 0 \right\rangle, \quad (2.14)$$

where $|0\rangle$ is the vacuum state. As we will see in (3.3), we have a single valence bond in each cell. Therefore, the filling of the ground state is $1/N_a$, where N_a is the number of sites in the unit cell. In Secs. IV and V, we use the second term in (2.10) as the Hamiltonian and denote it by H_S . The unique ground state of the Hamiltonian H_S is given by (2.14) with the energy E_0 in (2.12).

III. GEOMETRIC REPRESENTATION OF THE CORRELATION FUNCTIONS

We describe the geometric representation of the norm of the ground state and the correlation functions which was formulated by Tasaki [24] in arbitrary dimensions. The geometric representation of the norm is described in Refs. [4,9,25] for the lattice composed of d -sites only. Here, we have the lattice with both p - and d -sites. The ground state (2.14) can be written

$$|\Phi_{G.S.}\rangle = \mathcal{P} \prod_{n=1}^N \sum_{r,s \in C_n} \lambda_r^* \lambda_s^* c_{r,\uparrow}^\dagger c_{s,\downarrow}^\dagger |0\rangle = \mathcal{P} \prod_{n=1}^N \sum_{r \leq s \in C_n} \lambda_{rs}^* b_{r,s}^\dagger |0\rangle, \quad (3.1)$$

where

$$b_{r,s}^\dagger = \begin{cases} c_{r,\uparrow}^\dagger c_{s,\downarrow}^\dagger + c_{s,\uparrow}^\dagger c_{r,\downarrow}^\dagger & \text{for } r \neq s \\ c_{r,\uparrow}^\dagger c_{s,\downarrow}^\dagger, & \text{for } r = s, \end{cases}$$

and

$$\lambda_{rs}^* = \lambda_r^* \lambda_s^*.$$

The operator $b_{r,s}^\dagger$ is the creation operator of the valence bond (i.e. a singlet pair) between sites r and s if $r \neq s$. It creates a doubly occupied site if $r = s$. They obey the commutation relations

$$[b_{r,s}, b_{t,u}] = [b_{r,s}^\dagger, b_{t,u}^\dagger] = [b_{r,s}^\dagger, b_{t,u}] = 0, \quad (3.2)$$

where r, s, t , and u are different sites one another. This operator satisfies the relation $b_{r,s}^\dagger = b_{s,r}^\dagger$ and the ground state (3.1) is a hopping-dominated RVB state according to the terminology of [9]. It is different from the tunneling-dominated RVB states [9,10,11,12,13,14,15,16].

Now we rewrite the ground state (3.1) in a convenient form for diagrammatic evaluations of the norm and the correlation functions. The diagrammatic method was first introduced by Rumer [26] and Pauling [27]. We denote a valence bond by $\{x, y\}$, and a doubly occupied site by $\{x, x\}$ which is regarded as a self-closed bond (Fig. 2). Since a self-closed bond is actually a doubly occupied site, it is allowed only at p -sites. Let a valence-bond configuration V be a set of N bonds constructed by choosing a single bond from each cell. We show examples in Figs. 3(a) and (b). The bonds do not share a d -site since it can have at most one electron. A p -site is shared by at most two bonds. In this way, the projection $\mathcal{P}$ defined by (2.4) and (2.13) is automatically taken into account. We denote by $\mathcal{V}$ the set of all the possible valence-bond configurations. The ground state (3.1) is rearranged, and written as

$$|\Phi_{G.S.}\rangle = \sum_{V \in \mathcal{V}} \prod_{\{x,y\} \in V} \lambda_{x,y}^* b_{x,y}^\dagger |0\rangle. \quad (3.3)$$

A. Norm of the ground state

From (3.3), the norm of the ground state is

$$\langle \Phi_{G.S.} | \Phi_{G.S.} \rangle = \sum_{V \in \mathcal{V}} \sum_{V' \in \mathcal{V}} \lambda(V') \lambda^*(V) \left\langle 0 \left| \prod_{\{x',y'\} \in V'} b_{x',y'} \prod_{\{x,y\} \in V} b_{x,y}^\dagger \right| 0 \right\rangle, \quad (3.4)$$

where $\lambda(V) = \prod_{\{x,y\} \in V} \lambda_{x,y}$. Let us consider a graph $V \cup V'$ in the expectation value. We call a bond which belongs to V' as a “bra-bond” and one which belongs to V as a “ket-bond” (Fig. 2). We only consider graphs $V \cup V'$ in which numbers of “bra-bonds” and “ket-bonds” are equal at every sites. (An example is shown in Fig. 3(c).) Otherwise, the expectation value is vanishing, since the numbers of the creation and annihilation operators are different at the site.

The graph $V \cup V'$ can be decomposed into connected subgraphs, since the operators $b_{x',y'}$ and $b_{x,y}^\dagger$ commute (see (3.2)). An example is shown in Fig. 3(d)-(g). We denote the number of the subgraphs by $n(V \cup V')$. This decomposition is written

$$V \cup V' = \sum_{i=1}^{n(V \cup V')} U_i \cup U'_i, \quad (3.5)$$

where $U_i \subset V$ and $U'_i \subset V'$.

By noting that $b_{x',y'}$ and $b_{x,y}^\dagger$ commute with each other for distinct x, y, x' , and y' (see (3.2)), we find that the expectation value in (3.4) can be factorized into parts corresponding to connected subgraphs. Thus, we have

$$\langle \Phi_{G.S.} | \Phi_{G.S.} \rangle = \sum_{V, V' \in \mathcal{V}} \left\{ \prod_{i=1}^{n(V \cup V')} \lambda(U'_i) \lambda^*(U_i) \left\langle 0 \left| \prod_{\{x', y'\} \in U'_i} b_{x', y'} \prod_{\{x, y\} \in U_i} b_{x, y}^\dagger \right| 0 \right\rangle \right\}. \quad (3.6)$$

We note that each U_i, U'_i in (3.6) depends on the whole configurations V, V' , and $V \cup V'$.

It sometimes happen that two “bra-bonds” and two “ket-bonds” are connected to a single p -site in a connected subgraph $U_i \cup U'_i$. For our calculations, it is convenient to eliminate such sites. This is done by using the identity $b_{x,y}^\dagger b_{y,z}^\dagger = -b_{y,y}^\dagger b_{x,z}^\dagger$ (see Fig. 4). Examples of eliminations of such sites are shown in Figs. 5 diagrammatically. The procedure in Fig. 5(a) generates a minus sign. We assign the sign to the non-closed bond. We shall always apply this procedure hereafter and it should be understood implicitly. After this procedure, the subgraph $U_i \cup U'_i$ may be decomposed into several graphs. We denote the number of the graphs by $n(U_i \cup U'_i)$. The decomposition is unique and is written

$$U_i \cup U'_i \rightarrow \sum_{j=1}^{n(U_i \cup U'_i)} W_j \cup W'_j. \quad (3.7)$$

The arrow indicates that W_j, W'_j are not necessarily subsets of $U_i \cup U'_i$. We only have three kinds of graphs $W_j \cup W'_j$: self-closed bonds (Fig. 6(a)), degenerate loops which consist of a pair of bonds (Fig. 6(b)), and non-degenerate loops which consist of even number of distinct bonds (Fig. 6(c)). We call the graph $W_j \cup W'_j$ loop. From the decomposition (3.7), we have

$$\left\langle 0 \left| \prod_{\{x', y'\} \in U'_i} b_{x', y'} \prod_{\{x, y\} \in U_i} b_{x, y}^\dagger \right| 0 \right\rangle = \prod_{j=1}^{n(U_i \cup U'_i)} (-1)^{m_j} w_j, \quad (3.8)$$

where m_j is the number of the procedures shown in Fig. 5(a) and

$$w_j = \left\langle 0 \left| \prod_{\{x', y'\} \in W'_j} b_{x', y'} \prod_{\{x, y\} \in W_j} b_{x, y}^\dagger \right| 0 \right\rangle. \quad (3.9)$$

We call it weight. The value is classified to

$$w_j = \begin{cases} 1 & \text{if } W_j \cup W'_j \text{ is a pair of the self-closed bonds (Fig. 6(a))} \\ 2 & \text{if } W_j \cup W'_j \text{ is a degenerate loop (Fig. 6(b))} \\ 2(-1)^{l_j/2-1} & \text{if } W_j \cup W'_j \text{ is a non-degenerate loop (Fig. 6(c)),} \end{cases} \quad (3.10)$$

where l_j is the number of the bonds in the j -th non-degenerate loop. These weights are derived in Appendix B. Now the norm of the ground state (3.6) is written

$$\langle \Phi_{G.S.} | \Phi_{G.S.} \rangle = \sum_{V, V' \in \mathcal{V}} \left\{ \prod_{i=1}^{n(V \cup V')} \left[\prod_{j=1}^{n(U_i \cup U'_i)} \lambda(W'_j) \lambda^*(W_j) (-1)^{m_j} w_j \right] \right\}. \quad (3.11)$$

B. Spin correlation function

The spin correlation function is given by

$$\langle S_x^z S_y^z \rangle = \frac{\langle \Phi_{G.S.} | S_x^z S_y^z | \Phi_{G.S.} \rangle}{\langle \Phi_{G.S.} | \Phi_{G.S.} \rangle}, \quad (3.12)$$

where $S_x^z = (c_{x,\uparrow}^\dagger c_{x,\uparrow} - c_{x,\downarrow}^\dagger c_{x,\downarrow})/2$ is the z -component of the spin operator on site x . From (3.3), the numerator is written

$$\langle \Phi_{G.S.} | S_x^z S_y^z | \Phi_{G.S.} \rangle = \sum_{V \in \mathcal{V}} \sum_{V' \in \mathcal{V}} \lambda(V') \lambda^*(V) \left\langle 0 \left| \left(\prod_{\{u',v'\} \in V'} b_{u',v'} \right) S_x^z S_y^z \prod_{\{u,v\} \in V} b_{u,v}^\dagger \right| 0 \right\rangle. \quad (3.13)$$

From the commutation relations (3.2) and $[S_x^z, b_{u,v}] = [S_x^z, b_{u,v}^\dagger] = 0$ where x, u , and v are different sites one another, we can decompose the graph $V \cup V'$ into connected subgraphs $U_i \cup U'_i$ as we did in subsection III A. We only need to consider the case where sites x and y belong to a single subgraph denoted as $U^{(x,y)} \cup U'^{(x,y)}$. Otherwise, the expectation value in (3.13) is vanishing. The decomposition is written

$$V \cup V' = U^{(x,y)} \cup U'^{(x,y)} + \sum_{i=1}^{n(V \cup V')-1} U_i \cup U'_i. \quad (3.14)$$

After the elimination of p -sites with four non-closed bonds, we only need to consider the case where sites x and y belong to a single loop (Fig. 7) denoted as $W^{(x,y)} \cup W'^{(x,y)}$. Otherwise, the expectation value in (3.13) is vanishing. We have

$$\begin{aligned} V \cup V' &\rightarrow W^{(x,y)} \cup W'^{(x,y)} + \sum_{j=1}^{n(U^{(x,y)} \cup U'^{(x,y)})-1} W_j \cup W'_j + \sum_{i=1}^{n(V \cup V')-1} \left(\sum_{j=1}^{n(U_i \cup U'_i)} W_j \cup W'_j \right) \end{aligned} \quad (3.15)$$

$$= W^{(x,y)} \cup W'^{(x,y)} + \sum_{j=1}^{\mathcal{N}_W} W_j \cup W'_j. \quad (3.16)$$

We note that each W_j, W'_j in the second term of (3.15) depends on the graphs $U^{(x,y)}, U'^{(x,y)}$, and $U^{(x,y)} \cup U'^{(x,y)}$, and those in the third term depends on the graphs U_i, U'_i , and $U_i \cup U'_i$. We denote the total number of the loops $W_j \cup W'_j$ in the second and the third terms of (3.15) by $\mathcal{N}_W$. Their labelings in (3.16) were rearranged. The weight for the loop $W^{(x,y)} \cup W'^{(x,y)}$ is

$$\begin{aligned} w(x,y) &= \left\langle 0 \left| \left(\prod_{\{z',w'\} \in W'^{(x,y)}} b_{z',w'} \right) S_x^z S_y^z \prod_{\{z,w\} \in W^{(x,y)}} b_{z,w}^\dagger \right| 0 \right\rangle \\ &= (-1)^{d(x,y)} \frac{1}{4} \left\langle 0 \left| \prod_{\{z',w'\} \in W'^{(x,y)}} b_{z',w'} \prod_{\{z,w\} \in W^{(x,y)}} b_{z,w}^\dagger \right| 0 \right\rangle \\ &= (-1)^{d(x,y)} \frac{1}{4} w \end{aligned} \quad (3.17)$$

where $d(x,y)$ is the number of the bonds between x and y along the loop and w is given by (3.10). A derivation is shown in Appendix C. From (3.8), (3.9), (3.16), and (3.17), we obtain

$$\begin{aligned} &\langle \Phi_{G.S.} | S_x^z S_y^z | \Phi_{G.S.} \rangle \\ &= \sum_{V, V' \in \mathcal{V}} \left\{ (-1)^{d(x,y)} \frac{1}{4} \prod_{i=1}^{n(V \cup V')} \lambda(U'_i) \lambda^*(U_i) \left\langle 0 \left| \prod_{\{x',y'\} \in U'_i} b_{x',y'} \prod_{\{x,y\} \in U_i} b_{x,y}^\dagger \right| 0 \right\rangle \right\} \end{aligned} \quad (3.18)$$

$$= \sum_{V, V' \in \mathcal{V}} \left\{ (-1)^{d(x,y)} \frac{1}{4} \prod_{i=1}^{n(V \cup V')} \left[\prod_{j=1}^{n(U_j \cup U'_j)} \lambda(W'_j) \lambda^*(W_j) (-1)^{m_j} w_j \right] \right\}, \quad (3.19)$$

where the weight for the loop $W^{(x,y)} \cup W'^{(x,y)}$ is included in the product.

C. Correlation function $\langle c_{x,\sigma} c_{y,\sigma}^\dagger \rangle$

We evaluate the correlation function defined by

$$\langle c_{x,\sigma} c_{y,\sigma}^\dagger \rangle = \frac{\langle \Phi_{G.S.} | c_{x,\sigma} c_{y,\sigma}^\dagger | \Phi_{G.S.} \rangle}{\langle \Phi_{G.S.} | \Phi_{G.S.} \rangle}. \quad (3.20)$$

From (3.3), the numerator is written

$$\langle \Phi_{G.S.} | c_{x,\sigma} c_{y,\sigma}^\dagger | \Phi_{G.S.} \rangle = \sum_{V \in \mathcal{V}} \sum_{V' \in \mathcal{V}} \lambda(V') \lambda^*(V) \left\langle 0 \left| \left(\prod_{\{u',v'\} \in V'} b_{u',v'} \right) c_{x,\sigma} c_{y,\sigma}^\dagger \prod_{\{u,v\} \in V} b_{u,v}^\dagger \right| 0 \right\rangle. \quad (3.21)$$

We decompose the graph $V \cup V'$ into connected subgraphs using the commutation relations (3.2) and $[c_{z,\sigma}, b_{x,y}] = [c_{z,\sigma}, b_{x,y}^\dagger] = [c_{z,\sigma}^\dagger, b_{x,y}] = 0$ where $z \neq x$ and $z \neq y$ and obtain (3.14). After the elimination of p -sites with four non-closed bonds, we only need to consider the case where sites x and y belong to a single graph and they satisfy one of the following four conditions: (i) site $x(y)$ with one non-closed ket(bra)bond; (ii) site $x(y)$ with one non-closed bra(ket)bond and one self-closed ket(bra) bond. (See Figs. 8 where a site with a pentagon represents the operator $c_{x,\sigma}$ or $c_{y,\sigma}^\dagger$.) Otherwise, the expectation value is vanishing. It is convenient to eliminate type (ii) sites using the identity $c_{x,\sigma}^\dagger b_{x,y}^\dagger = -c_{y,\sigma}^\dagger b_{x,x}^\dagger$ which is represented diagrammatically in Fig. 9. The results are shown in Figs. 10(a) and (b). After this procedure, the graph $W^{(x',y')} \cup W'^{(x',y')}$ in (3.14) is a line where “bra-bond” and “ket-bond” are placed alternately and x' and y' are always at the end of the line (Fig. 10(c)). The weight is

$$w(x', y') = \left\langle 0 \left| \left(\prod_{\{u',v'\} \in W'^{(x',y')}} b_{u',v'} \right) c_{x',\sigma} c_{y',\sigma}^\dagger \prod_{\{u,v\} \in W^{(x',y')}} b_{u,v}^\dagger \right| 0 \right\rangle = (-1)^{l(x',y')/2}, \quad (3.22)$$

where $l(x', y')$ is the number of the bonds (see Appendix D). Thus we have

$$\begin{aligned} & \langle \Phi_{G.S.} | c_{x,\sigma} c_{y,\sigma}^\dagger | \Phi_{G.S.} \rangle \\ &= \sum_{V, V' \in \mathcal{V}} \left\{ \lambda(U'^{(x,y)}) \lambda^*(U^{(x,y)}) \left\langle 0 \left| \left(\prod_{\{z',w'\} \in U'^{(x,y)}} b_{z',w'} \right) c_{x,\sigma} c_{y,\sigma}^\dagger \prod_{\{z,w\} \in U^{(x,y)}} b_{z,w}^\dagger \right| 0 \right\rangle \right. \\ & \quad \times \left. \prod_{i=1}^{n(V \cup V')-1} \left[\lambda(U'_i) \lambda^*(U_i) \left\langle 0 \left| \prod_{\{u',v'\} \in U'_i} b_{u',v'} \prod_{\{u,v\} \in U_i} b_{u,v}^\dagger \right| 0 \right\rangle \right] \right\} \quad (3.23) \end{aligned}$$

$$= \sum_{V, V' \in \mathcal{V}} \left\{ \lambda(W'^{(x',y')}) \lambda^*(W^{(x',y')}) (-1)^{l(x',y')/2+m} \prod_{j=1}^{\mathcal{N}_W} \lambda(W'_j) \lambda^*(W_j) (-1)^{m_j} w_j \right\}, \quad (3.24)$$

where m is the number of the procedures shown in Fig. 5(a) for the subgraph $U^{(x,y)} \cup U'^{(x,y)}$.

D. Density correlation function

We first evaluate the expectation value of the number operator

$$\langle n_{x,\sigma} \rangle = \frac{\langle \Phi_{G.S.} | n_{x,\sigma} | \Phi_{G.S.} \rangle}{\langle \Phi_{G.S.} | \Phi_{G.S.} \rangle}. \quad (3.25)$$

From (3.3), the numerator is written

$$\langle \Phi_{G.S.} | n_{x,\sigma} | \Phi_{G.S.} \rangle = \sum_{V \in \mathcal{V}} \sum_{V' \in \mathcal{V}} \lambda(V') \lambda^*(V) \left\langle 0 \left| \left(\prod_{\{u',v'\} \in V'} b_{u',v'} \right) n_{x,\sigma} \prod_{\{u,v\} \in V} b_{u,v}^\dagger \right| 0 \right\rangle. \quad (3.26)$$

We only need to consider the graph $V \cup V'$ which contains the site x . Otherwise, the expectation value is vanishing. The similar calculation to that in Sec. III B leads

$$\begin{aligned} V \cup V' &= U^{(x)} \cup U'^{(x)} + \sum_{i=1}^{n(V \cup V')-1} U_i \cup U'_i \\ &\rightarrow W^{(x)} \cup W'^{(x)} + \sum_{j=1}^{n(U^{(x)} \cup U'^{(x)})-1} W_j \cup W'_j + \sum_{i=1}^{n(V \cup V')-1} \left(\sum_{j=1}^{n(U_i \cup U'_i)} W_j \cup W'_j \right) \\ &= W^{(x)} \cup W'^{(x)} + \sum_{j=1}^{\mathcal{N}_W} W_j \cup W'_j, \end{aligned} \quad (3.27)$$

where $U^{(x)} \cup U'^{(x)}$ is a subgraph with the site x , and $W^{(x)} \cup W'^{(x)}$ is a loop with the site x after the elimination of p -sites with four non-closed bonds. We distinguish two kinds of loops: (i) site x with self-closed bonds; (ii) site x with one non-closed “bra-bond” and one non-closed “ket-bond”. (See Figs. 11, where a site with a circle represents the number operator.) (We note that a subgraph $U^{(x)} \cup U'^{(x)}$ with four non-closed bonds at the site x is decomposed into type (ii) graph and loops.) The weight is

$$\begin{aligned} w(x) &= \left\langle 0 \left| \left(\prod_{\{z',w'\} \in W'^{(x)}} b_{z',w'} \right) n_{x,\sigma} \prod_{\{z,w\} \in W^{(x)}} b_{z,w}^\dagger \right| 0 \right\rangle \\ &= \begin{cases} 1 & \text{for (i)} \\ (-1)^{l(x)/2-1} & \text{for (ii)}, \end{cases} \end{aligned} \quad (3.28)$$

where $l(x)$ is the number of the bonds in the graph. A derivation is given in Appendix E. From (3.8), (3.9), (3.27), and (3.28), we obtain

$$\begin{aligned} &\langle \Phi_{G.S.} | n_{x,\sigma} | \Phi_{G.S.} \rangle \\ &= \sum_{V,V' \in \mathcal{V}} \left\{ \lambda(U'^{(x)}) \lambda^*(U^{(x)}) \left\langle 0 \left| \left(\prod_{\{z',w'\} \in U'^{(x)}} b_{z',w'} \right) n_{x,\sigma} \prod_{\{z,w\} \in U^{(x)}} b_{z,w}^\dagger \right| 0 \right\rangle \right. \\ &\quad \times \left. \prod_{i=1}^{n(V \cup V')-1} \left[\lambda(U_i) \lambda^*(U_i) \left\langle 0 \left| \prod_{\{u',v'\} \in U'_i} b_{u',v'} \prod_{\{u,v\} \in U_i} b_{u,v}^\dagger \right| 0 \right\rangle \right] \right\} \end{aligned} \quad (3.29)$$

$$= \sum_{V,V' \in \mathcal{V}} \left\{ \lambda(W_j'^{(x)}) \lambda^*(W_j^{(x)}) (-1)^{m_j} w(x) \prod_{j=1}^{\mathcal{N}_W} \lambda(W_j') \lambda^*(W_j) (-1)^{m_j} w_j \right\}. \quad (3.30)$$

The density correlation function is

$$\begin{aligned} \langle \delta n_x \delta n_y \rangle &= \langle (n_x - \langle n_x \rangle) (n_y - \langle n_y \rangle) \rangle \\ &= \langle n_x n_y \rangle - \langle n_x \rangle \langle n_y \rangle \\ &= \frac{\langle \Phi_{G.S.} | n_x n_y | \Phi_{G.S.} \rangle}{\langle \Phi_{G.S.} | \Phi_{G.S.} \rangle} - \frac{\langle \Phi_{G.S.} | n_x | \Phi_{G.S.} \rangle \langle \Phi_{G.S.} | n_y | \Phi_{G.S.} \rangle}{(\langle \Phi_{G.S.} | \Phi_{G.S.} \rangle)^2} \\ &= 4 \left[\frac{D(x, y; \sigma)}{\langle \Phi_{G.S.} | \Phi_{G.S.} \rangle} - \langle n_{x,\sigma} \rangle \langle n_{y,\sigma} \rangle \right], \end{aligned} \quad (3.31)$$

where

$$D(x, y; \sigma) = \frac{1}{2} \left\langle \Phi_{G.S.} \left| c_{x,\sigma} c_{y,\sigma} c_{y,\sigma}^\dagger c_{x,\sigma}^\dagger + c_{x,\sigma} c_{y,-\sigma} c_{y,-\sigma}^\dagger c_{x,\sigma}^\dagger \right| \Phi_{G.S.} \right\rangle. \quad (3.32)$$

From (3.3), we have

$$D(x, y; \sigma) = \sum_{V \in \mathcal{V}} \sum_{V' \in \mathcal{V}} \lambda(V') \lambda^*(V) \times \left\langle 0 \left| \left(\prod_{\{u',v'\} \in V'} b_{u',v'} \right) \frac{1}{2} \left(c_{x,\sigma} c_{y,\sigma} c_{y,\sigma}^\dagger c_{x,\sigma}^\dagger + c_{x,\sigma} c_{y,-\sigma} c_{y,-\sigma}^\dagger c_{x,\sigma}^\dagger \right) \prod_{\{u,v\} \in V} b_{u,v}^\dagger \right| 0 \right\rangle. \quad (3.33)$$

We only need to consider the graph $V \cup V'$ which contains the sites x and y . Otherwise, the expectation value is vanishing. The similar calculation to that in Sec. IIIB leads (3.16) where $W^{(x,y)} \cup W'^{(x,y)}$ is a loop (or two loops) which contain(s) the sites x and y . We classify the loops $W^{(x,y)} \cup W'^{(x,y)}$ as (i) sites x and y each belongs to two distinct self-closed bonds, (ii) site x (y) belongs to the loop and site y (x) belongs to the self-closed bonds, (iii) sites x and y each belongs to two distinct loops, and (iv) sites x and y belong to a single graph. (See Figs. 12.) Otherwise, the expectation value is vanishing. The weight is

$$w(x, y; \sigma) = \left\langle 0 \left| \left(\prod_{\{u',v'\} \in W'^{(x,y)}} b_{u',v'} \right) \frac{1}{2} \left(c_{x,\sigma} c_{y,\sigma} c_{y,\sigma}^\dagger c_{x,\sigma}^\dagger + c_{x,\sigma} c_{y,-\sigma} c_{y,-\sigma}^\dagger c_{x,\sigma}^\dagger \right) \prod_{\{u,v\} \in W^{(x,y)}} b_{u,v}^\dagger \right| 0 \right\rangle \quad (3.34)$$

$$= \begin{cases} 1 & \text{for (i)} \\ (-1)^{l(x)/2-1} & \text{for (ii) when the site } x \text{ belongs to the loop} \\ (-1)^{l(x)/2-1} \times (-1)^{l_i(y)/2-1} & \text{for (iii)} \\ (-1)^{l(x,y)/2-1}/2 & \text{for (iv),} \end{cases} \quad (3.35)$$

where $l(x)$ and $l(x, y)$ are the numbers of the bonds. A derivation is given in Appendix F. From (3.8), (3.9), and (3.35), we obtain

$$D(x, y; \sigma) = \sum_{V, V' \in \mathcal{V}} \left\{ \lambda(U'^{(x,y)}) \lambda^*(U^{(x,y)}) \times \left\langle 0 \left| \left(\prod_{\{z',w'\} \in U'^{(x,y)}} b_{z',w'} \right) \frac{1}{2} \left(c_{x,\sigma} c_{y,\sigma} c_{y,\sigma}^\dagger c_{x,\sigma}^\dagger + c_{x,\sigma} c_{y,-\sigma} c_{y,-\sigma}^\dagger c_{x,\sigma}^\dagger \right) \prod_{\{z,w\} \in U^{(x,y)}} b_{z,w}^\dagger \right| 0 \right\rangle \right. \\ \left. \times \prod_{i=1}^{n(V \cup V')-1} \left[\lambda(U'_i) \lambda^*(U_i) \left\langle 0 \left| \prod_{\{u',v'\} \in W'_i} b_{u',v'} \prod_{\{u,v\} \in W_i} b_{u,v}^\dagger \right| 0 \right\rangle \right] \right\} \quad (3.36)$$

$$= \sum_{V, V' \in \mathcal{V}} \left\{ \lambda(W'^{(x,y)}) \lambda^*(W^{(x,y)}) (-1)^m w(x, y; \sigma) \prod_{j=1}^{\mathcal{N}_W} \lambda(W'_j) \lambda^*(W_j) (-1)^{m_j} w_j \right\}. \quad (3.37)$$

E. Singlet-pair correlation function

The singlet-pair correlation function is given by

$$\langle b_{x,y}^\dagger b_{u,v} \rangle = \frac{\langle \Phi_{G.S.} | b_{x,y}^\dagger b_{u,v} | \Phi_{G.S.} \rangle}{\langle \Phi_{G.S.} | \Phi_{G.S.} \rangle}. \quad (3.38)$$

From (3.3), we obtain

$$\begin{aligned}
& \langle \Phi_{G.S.} | b_{x,y}^\dagger b_{u,v} | \Phi_{G.S.} \rangle \\
&= \sum_{V \in \mathcal{V}} \sum_{V' \in \mathcal{V}} \lambda(V') \lambda^*(V) \left\langle 0 \left| \left(\prod_{\{x',y'\} \in V'} b_{x',y'} \right) b_{x,y}^\dagger b_{u,v} \prod_{\{x,y\} \in V} b_{x,y}^\dagger \right| 0 \right\rangle \\
&= \sum_{V, V' \in \mathcal{V}} \left\{ \prod_{i=1}^{n(V \cup V' \cup \{x,y\} \cup \{u,v\})} \lambda(U'_j) \lambda^*(U_j) \left\langle 0 \left| \left(\prod_{\{x',y'\} \in U'} b_{x',y'} \right) b_{x,y}^\dagger b_{u,v} \prod_{\{x,y\} \in U} b_{x,y}^\dagger \right| 0 \right\rangle \right\} \\
&\hspace{25em} (3.39)
\end{aligned}$$

$$= \sum_{V, V' \in \mathcal{V}} \left\{ \prod_{i=1}^{n(V \cup V' \cup \{x,y\} \cup \{u,v\})} \left[\prod_{j=1}^{n(U_i \cup U'_i)} \lambda(W'_j) \lambda^*(W_j) (-1)^{m_j} w_j \right] \right\}, \quad (3.40)$$

where V and V' satisfy the condition that the graph $V \cup V' \cup \{x, y\} \cup \{u, v\}$ consists of connected subgraphs.

IV. EXPLICIT CALCULATIONS OF THE CORRELATION FUNCTIONS

The results of Secs. II and III are valid in any dimensions. At the moment, however, a practical use of them is limited to models in one dimension in which the transfer matrix method can be applied. In this section, the equal-time correlation functions are evaluated exactly for one-dimensional models. We shall show the analytical procedures for obtaining them for Model A defined below in subsection IV A, illustrating the method in details. The results are shown for a system size N and in the thermodynamic limit. For Models B and C, we shall only show the results in the thermodynamic limit.

A. Model A

1. Hamiltonian

Let us consider a lattice constructed from cells with three sites. We have two lattices which satisfy the uniqueness condition of Ref. [5]. One of them, which we call Model A (the other is called Model B, see subsection IV C) is constructed by a cell with two d -sites and one p -site (Fig. 13(a)). Note that a cell is not a unit cell. A unit cell is composed of a d -site and a p -site. In the models constructed by the cell construction, Model A is the simplest one for the following two reasons. The structure of the lattice is the simplest. (We can construct lattices from cells with two sites. The exact ground state, however, contains two electrons per site and is fully-filled.) The calculation of the correlation function is easier than that of Model B.

The cell Hamiltonian (2.2) is obtained by choosing $\alpha_{n,\sigma}^{(A)} = \sum_{r=1}^3 \lambda_r c_{r,\sigma} \equiv \lambda_1 c_{1,\sigma}^d + \lambda_2 c_{2,\sigma}^d + \lambda_3 c_{3,\sigma}^p$ in (2.3) and setting $\lambda_3 = 1$ without loss of generality (see Fig. 13(a) for intra-cell index). Here $c_{r,\sigma}^d$ ($c_{r,\sigma}^p$) is the annihilation operator on a d (p)-site. The full Hamiltonian is obtained by identifying the site 1 in the $(n-1)$ -th cell with the site 2 in the n -th cell (Fig. 13(b)). The Hamiltonian is

$$H_S = \mathcal{P} \sum_{\sigma=\uparrow,\downarrow} \left\{ \sum_{n=1}^N \left[(-\lambda_1 \lambda_2 c_{n+1,\sigma}^d \dagger c_{n,\sigma}^d - \lambda_1 c_{n+1,\sigma}^d \dagger c_{n,\sigma}^p - \lambda_2 c_{n,\sigma}^d \dagger c_{n,\sigma}^p + h.c.) \right. \right. \\ \left. \left. + \epsilon_n^d c_{n,\sigma}^d \dagger c_{n,\sigma}^d + \epsilon^p c_{n,\sigma}^p \dagger c_{n,\sigma}^p \right] + \epsilon_{N+1}^d c_{N+1,\sigma}^d \dagger c_{N+1,\sigma}^d \right\} \mathcal{P}, \quad (4.1)$$

where the on-site potentials are $\epsilon_1^d = -2\lambda_2^2$, $\epsilon_n^d = -2(\lambda_1^2 + \lambda_2^2)$ ($2 \leq n \leq N$), $\epsilon_{N+1}^d = -2\lambda_1^2$, and $\epsilon^p = -1$. A unit cell is labeled by n . The ground state is

$$|\Phi_{G.S.}^A\rangle = \mathcal{P} \prod_{n=1}^N \prod_{\sigma=\uparrow,\downarrow} \alpha_{n,\sigma}^{(A)\dagger} |0\rangle \quad (4.2)$$

$$= \mathcal{P} \prod_{n=1}^N \prod_{\sigma=\uparrow,\downarrow} \left(\lambda_1 c_{n,\sigma}^d \dagger + \lambda_2 c_{n+1,\sigma}^d \dagger + c_{n,\sigma}^p \dagger \right) |0\rangle \quad (4.3)$$

which is a half-filled state.

2. Band structure in the single-electron problem

Before studying the ground state (4.3), we investigate the corresponding non-interacting system. We consider the system with an even number of unit cells under the periodic boundary condition $c_{N+1}^d = c_1^d$. A one-particle state can be written

$$|\Phi_F\rangle = \sum_n \sum_{\alpha=p,d} \varphi_n^\alpha c_{n,\uparrow}^\alpha \dagger |0\rangle, \quad (4.4)$$

where φ_n^α are complex coefficients. The single-electron Schrödinger equation $H|\Phi_F\rangle = E|\Phi_F\rangle$, where E is the energy eigenvalue, corresponding to the Hamiltonian (4.1) is

$$\begin{cases} E\varphi_n^d = -\lambda_1\lambda_2(\varphi_{n-1}^d + \varphi_{n+1}^d) - 2(\lambda_1^2 + \lambda_2^2)\varphi_n^d - \lambda_1\varphi_{n-1}^p - \lambda_2\varphi_{n+1}^p \\ E\varphi_n^p = -\lambda_1\varphi_{n-1}^d - \lambda_2\varphi_{n+1}^d - \varphi_n^p \end{cases} \quad (4.5)$$

From the Fourier transformation $\varphi_n^\alpha = \frac{1}{\sqrt{N}} \sum_k e^{ikn} \varphi_k^\alpha$ where

$$k = 0, \pm\frac{2\pi}{N}, \pm\frac{4\pi}{N}, \dots, \pm 2\pi\frac{\frac{N}{2}-1}{N}, \pi, \quad (4.6)$$

the Schrödinger equation in the momentum space is

$$\begin{cases} E\varphi_k^d = -2(\lambda_1\lambda_2 \cos k + \lambda_1^2 + \lambda_2^2)\varphi_k^d - (\lambda_1 + \lambda_2 e^{-ik})\varphi_k^p \\ E\varphi_k^p = -(\lambda_1 + \lambda_2 e^{ik})\varphi_k^d - \varphi_k^p \end{cases} \quad (4.7)$$

The eigen energies are

$$E_\pm = -\frac{1}{2} \left[2\lambda_1\lambda_2 \cos k + 2\lambda_1^2 + \lambda_2^2 + 1 \mp \sqrt{(2\lambda_1\lambda_2 \cos k + 2\lambda_1^2 + 2\lambda_2^2)^2 - 4(\lambda_1^2 + \lambda_2^2)} \right], \quad (4.8)$$

where $-$, $+$ are the band index with $-$ (*resp.* $+$) corresponding to the $+$ (*resp.* $-$) sign. The energy gap between two bands is $\Delta = \sqrt{(2\lambda_1\lambda_2 - 1)(1 + 4\lambda_1^2 - 2\lambda_1\lambda_2 + 4\lambda_2^2)}$. When $2\lambda_1\lambda_2 - 1 = 0$, the gap closes at $k = \pi$. (See Fig. 14.)

In the ground state (4.3), there are $2N$ electrons. Since there are $2N$ sites in the lattice, the electron number corresponds to full-filling of the lower band. Therefore, the ground state of the non-interactiong system is insulating for $2\lambda_1\lambda_2 - 1 \neq 0$. It is metallic when $2\lambda_1\lambda_2 - 1 = 0$.

3. Norm of the ground state

Before calculating the correlation functions, we evaluate the norm of the ground state (4.3), since the state is not normalized. For the sake of convenience, we draw the lattice shown in Fig. 13(b) as Fig. 13(c). The ground state admits the geometric representation (3.3), where an example of the valence-bond configuration V is shown in Fig. 15(a). The geometric representation of the norm is (3.6), where an example of the graph $V \cup V'$ is shown in Fig. 15(b). We first evaluate the contribution from a graph $V \cup V'$. It can be decomposed into the subgraphs $U_i \cup U'_i$ ($i = 1, 2, \dots, n(V \cup V')$). No loop extends over more than two cells and there is no p -site with four bonds, since the sites which is identified in the cell construction are d -sites. We do not need the procedures shown in Figs. 5. Therefore, the graph $U_i \cup U'_i$ cannot be decomposed further and we find $n(U_i \cup U'_i) = 1$ in (3.7) and $m_j = 0$ in (3.11). The cells with the graph are classified to four kinds (Figs. 16(a)-(d)). Consider the graph shown in Fig. 16(a). From (3.10), the weight for the degenerate loop is 2 and the contribution from $\lambda(U'_i)\lambda^*(U_i)$ in (3.11) is λ_2^2 . Therefore, the contribution from the graph is $2\lambda_2^2$. For other graphs see Figs. 16.

The sum over the graph $V \cup V'$ in (3.6) is equivalent to that over all the combination of above four kinds of cells under the restriction that a d -site has at most two valence-bonds. (The restriction means, for example, that the identification of the right d -site in Fig. 16(a) with the left d -site in Fig. 16(c) is forbidden.) Hereafter we shall always take into account the restriction and it should be understood implicitly. To evaluate the sum we use the transfer matrix method. We have to distinguish two cases due to the restriction. Let A_n and B_n be the quantity defined by the right-hand side of (3.6) on the lattice Λ_n . For A_n , the sum is taken over all the combination of the cells shown in Fig. 16 with the restriction that the n -th cell is represented by Fig. 16(a) or (b). For B_n , the sum is taken as was done for A_n with the restriction that the n -th cell is represented by (c) or (d). They are represented diagrammatically

$$A_n = \quad (4.9)$$

$$B_n = . \quad (4.10)$$

We note that the norm in the system size N is

$$\langle \Phi_{G.S.} | \Phi_{G.S.} \rangle = A_N + B_N. \quad (4.11)$$

Given A_{n-1} and B_{n-1} , we can form A_n and B_n by attaching them to the n -th cell. Let us consider A_n first. When the n -th cell is represented by Fig. 16(a), we can attach A_{n-1} and cannot attach B_{n-1} . When the n -th cell is represented by Fig. 16(b), we can attach A_{n-1} or B_{n-1} to it. Thus we have the recursion relation

$$\begin{aligned} A_n &= \\ &= 2\lambda_2^2 A_{n-1} + A_{n-1} + B_{n-1}. \end{aligned} \quad (4.12)$$

For B_n the similar calculation leads

$$\begin{aligned} B_n &= \\ &= 2\lambda_1^2 A_{n-1} + 2\lambda_1^2 B_{n-1} + 2\lambda_1^2 \lambda_2^2 A_{n-1}. \end{aligned} \quad (4.13)$$

They are conveniently written in a matrix form as

$$\begin{pmatrix} A_n \\ B_n \end{pmatrix} = \mathbf{T}_n \begin{pmatrix} A_{n-1} \\ B_{n-1} \end{pmatrix}, \quad \mathbf{T}_n = \begin{pmatrix} 1 + 2\lambda_2^2 & 1 \\ 2\lambda_1^2 + 2\lambda_1^2 \lambda_2^2 & 2\lambda_1^2 \end{pmatrix}. \quad (4.14)$$

The initial vector is $\vec{I} \equiv (A_0, B_0)^T = (1, 0)^T$, since any cell in Fig. 16 is allowed as the first cell. To obtain the quantity (4.11), we choose the final vector $\vec{F} \equiv (A_N, B_N)^T = (1, 1)^T$. Since the transfer matrix is not symmetric, it is convenient to diagonalize it using the right and left eigenvectors. The matrix can be diagonalized as

$$\mathbf{T}_n = \mathbf{R} \mathbf{D} \mathbf{R}^{-1} = \mathbf{L}^{-1} \mathbf{D} \mathbf{L}, \quad (4.15)$$

where

$$\mathbf{D} = \begin{pmatrix} e_1 & 0 \\ 0 & e_2 \end{pmatrix}, \quad \mathbf{R} = \begin{pmatrix} R_{11} & R_{12} \\ R_{21} & R_{22} \end{pmatrix}, \quad \mathbf{L} = \begin{pmatrix} L_{11} & L_{12} \\ L_{21} & L_{22} \end{pmatrix}, \quad (4.16)$$

where e_i are the eigenvalues of $\mathbf{T}_n$, $e_1 = (2\lambda_1^2 + 2\lambda_2^2 + 1 + \omega_1)/2$ and $e_2 = (2\lambda_1^2 + 2\lambda_2^2 + 1 - \omega_1)/2$ with $\omega_1 = \sqrt{4\lambda_1^4 + 4\lambda_2^4 + 4\lambda_1^2 + 4\lambda_2^2 + 1}$. They satisfy $e_1 > e_2 > 0$ for $\lambda_1 \neq 0$ and $\lambda_2 \neq 0$. We choose the left eigenvectors $\vec{L}_1 = (L_{11}, L_{12})^T$ and $\vec{L}_2 = (L_{21}, L_{22})^T$ corresponding to the eigenvalues e_1 and e_2 , respectively, and the right eigenvectors $\vec{R}_1 = (R_{11}, R_{21})^T$ and $\vec{R}_2 = (R_{12}, R_{22})^T$. Using the diagonal matrix $\mathbf{C} = \mathbf{L} \mathbf{R}$, we obtain

$$\mathbf{T}_n = \mathbf{R} \mathbf{D} \mathbf{C}^{-1} \mathbf{L}, \quad (4.17)$$

where

$$\mathbf{C} = \begin{pmatrix} c_1 & 0 \\ 0 & c_2 \end{pmatrix}. \quad (4.18)$$

From the quantities, the norm of the ground state in the system size N is

$$\begin{aligned} \langle \Phi_{G.S.}^A | \Phi_{G.S.}^A \rangle &= \vec{F}^T \mathbf{T}_N \cdots \mathbf{T}_2 \mathbf{T}_1 \vec{I} \\ &= \vec{F}^T \mathbf{R} \mathbf{D}^N \mathbf{C}^{-1} \mathbf{L} \vec{I} \\ &= \frac{1 + 2\lambda_1^2 + 2\lambda_2^2 + 4\lambda_1^2 \lambda_2^2 + \omega_1}{2\omega_1} e_1^N - \frac{1 + 2\lambda_1^2 + 2\lambda_2^2 + 4\lambda_1^2 \lambda_2^2 - \omega_1}{2\omega_1} e_2^N, \end{aligned} \quad (4.19)$$

where we used the relation $\mathbf{C}^{-1} \mathbf{L} \mathbf{R} = \mathbf{I}$, Here $\mathbf{I}$ is the identity matrix. In the thermodynamic limit, the eigenvalue e_1 dominates and we have

$$\langle \Phi_{G.S.}^A | \Phi_{G.S.}^A \rangle = \frac{1 + 2\lambda_1^2 + 2\lambda_2^2 + 4\lambda_1^2 \lambda_2^2 + \omega_1}{2\omega_1}. \quad (4.20)$$

4. Expectation value of the number operator

We calculate the occupation on a p -site $\langle n_{i,\sigma}^p \rangle$. The geometric representation of the expectation value is (3.29), where an example of the graph $V \cup V'$ is shown in Fig. 15(c). We do not need the procedures shown in Figs. 5, because there is no site with four bonds. Therefore, we find $n(U_i \cup U'_i) = 1$ in (3.27) and $m_j = 0$ in (3.30). In the representation, the operator $n_{i,\sigma}^p$ modifies the weight associated with the graph which contains the i -th cell. Therefore, we replace the transfer matrix $\mathbf{T}_i$ by $\mathbf{N}_i^{(p)}$ which is a matrix associated with the operator $n_{i,\sigma}^p$. The expectation value can be written

$$\langle \Phi_{G.S.}^A | n_{i,\sigma}^p | \Phi_{G.S.}^A \rangle = \vec{F}^T \mathbf{T}_N \cdots \mathbf{T}_{i+1} \mathbf{N}_i^{(p)} \mathbf{T}_{i-1} \cdots \mathbf{T}_1 \vec{I} \quad (4.21)$$

We derive the matrix $\mathbf{N}_i^{(p)}$. We have three kinds of graphs on the i -th cell (Fig. 17(a)-(c)). Let $A_i^{(p)}$ and $B_i^{(p)}$ be the quantity defined by the right-hand side of (3.29) on the lattice Λ_i . The restriction for the sum is that the i -th cell is represented either by Fig. 17(a) or (b) for $A_i^{(p)}$ and by (c) for $B_i^{(p)}$. They are represented diagrammatically

$$A_i^{(p)} = \quad (4.22)$$

$$B_i^{(p)} = , \quad (4.23)$$

and the recursion relations are

$$\begin{aligned} A_i^{(p)} &= \\ &= \lambda_2^2 A_{i-1} + A_{i-1} + B_{i-1} \end{aligned} \quad (4.24)$$

$$\begin{aligned} B_i^{(p)} &= \\ &= \lambda_1^2 A_{i-1} + \lambda_1^2 B_{i-1}. \end{aligned} \quad (4.25)$$

From (3.28), the loop with operator $n_{i,\sigma}$ has weight 1. It is written

$$\begin{pmatrix} A_i^{(p)} \\ B_i^{(p)} \end{pmatrix} = \mathbf{N}_i^{(p)} \begin{pmatrix} A_{i-1} \\ B_{i-1} \end{pmatrix}, \quad \mathbf{N}_i^{(p)} = \begin{pmatrix} 1 + \lambda_2^2 & 1 \\ \lambda_1^2 & \lambda_1^2 \end{pmatrix}. \quad (4.26)$$

From (4.51), (4.52), (4.19), and (4.26), we have

$$\begin{aligned} \langle n_{i,\sigma}^p \rangle &= \frac{\vec{F}^T \mathbf{T}^{N-i} \mathbf{N}_i^{(p)} \mathbf{T}^{i-1} \vec{I}}{\vec{F}^T \mathbf{T}^N \vec{I}} \\ &= \frac{\vec{F}^T \mathbf{R} \mathbf{D}^{N-i} \mathbf{C}^{-1} \mathbf{L} \mathbf{N}_i^{(p)} \mathbf{R} \mathbf{D}^{i-1} \mathbf{C}^{-1} \mathbf{L} \vec{I}}{\vec{F}^T \mathbf{R} \mathbf{D}^N \mathbf{C}^{-1} \mathbf{L} \vec{I}} \\ &= \frac{C_1 - C_2 \left(\frac{e_2}{e_1} \right)^i - C_3 \left(\frac{e_2}{e_1} \right)^{N-i} + C_4 \left(\frac{e_2}{e_1} \right)^N}{\frac{\omega_1}{2} \left\{ [(1 + 2\lambda_1^2)(1 + 2\lambda_2^2) + \omega_1] - [(1 + 2\lambda_1^2)(1 + 2\lambda_2^2) - \omega_1] \left(\frac{e_2}{e_1} \right)^N \right\}}, \end{aligned} \quad (4.27)$$

where

$$\begin{aligned} C_1 &= (e_1 - 2\lambda_1^2)(e_1 - 2\lambda_2^2)(e_1 - \lambda_1^2 - \lambda_2^2) \\ C_2 &= (e_1 - 2\lambda_2^2)(e_2 - 2\lambda_1^2)(e_1 e_2 - \lambda_2^2 e_1 - \lambda_1^2 e_2) / e_2 \\ C_3 &= (e_1 - 2\lambda_1^2)(e_2 - 2\lambda_2^2)(e_1 e_2 - \lambda_1^2 e_1 - \lambda_2^2 e_2) / e_1 \\ C_4 &= (e_2 - 2\lambda_1^2)(e_2 - 2\lambda_2^2)(e_2 - 2\lambda_1^2 - 2\lambda_2^2), \end{aligned}$$

in the system size N . In the thermodynamic limit, $N, i, N-i \rightarrow \infty$, we obtain

$$\langle n_{i,\sigma}^p \rangle = \frac{1}{2} \left(1 + \frac{1}{\omega_1} \right). \quad (4.28)$$

Since there are two electrons in a unit cell, from (4.28) we have the occupation on a d -site

$$\langle n_{i,\sigma}^d \rangle = \frac{1}{2} \left(1 - \frac{1}{\omega_1} \right). \quad (4.29)$$

We can also obtain the same quantity from the geometric representation of the expectation value. From the graphs shown in Fig. 17(d)-(f), we have the matrix associated with the operator $n_{i,\sigma}^d$

$$\mathbf{N}_i^{(d)} = \begin{pmatrix} \lambda_2^2 & 0 \\ \lambda_1^2 \lambda_2^2 & \lambda_1^2 \end{pmatrix}, \quad (4.30)$$

which will be used to obtain the density correlation function.

The results are shown in Figs. 18(a) and (b) for $\alpha = p$ and d , respectively. We consider the following cases: (i) $\lambda_1, \lambda_2 \gg 1$ ($\lambda_1 = \lambda_2$); (ii) $|\lambda_1|, |\lambda_2| \ll 1$ ($\lambda_1 = \lambda_2$); (iii) $|\lambda_1| \ll 1, \lambda_2 \gg 1$. For (i), on-site potentials satisfy the relation $\epsilon_d \ll \epsilon_p$. There is almost one electron per a site. For (ii), on-site potentials satisfy the relation $\epsilon_p < \epsilon_d$, $\epsilon_d - \epsilon_p \gg \lambda_1 \lambda_2$. The d -sites are almost empty. The p -sites are almost doubly occupied. For (iii), the system decouples to a collection of the pairs of p - and d -sites.

5. Two-point correlation functions

We calculate the density correlation function for the p -site. We first evaluate the first term in (3.31). The geometric representation of the expectation value is (3.36), where an example of the graph $V \cup V'$ is shown in Fig. 15(d). We do not need the procedures shown in Figs. 5, because there is no site with four bonds. Therefore, we find $n(U_i \cup U'_i) = 1$ in (3.15) and $m_j = 0$ in (3.37). In the representation, the operators modify the weight associated with the graph which contains cells between the cells i and j . From the derivation of the matrix $\mathbf{N}_i^{(p)}$, the expectation value is

$$D(x, y; \sigma) = \vec{F}^T \mathbf{T}_N \cdots \mathbf{T}_{j+1} \mathbf{N}_j^{(p)} \mathbf{T}_{j-1} \cdots \mathbf{T}_{i+1} \mathbf{N}_i^{(p)} \mathbf{T}_{i-1} \cdots \mathbf{T}_1 \vec{I}. \quad (4.31)$$

From (4.26) and (4.31), the first term in the right hand side of (3.31) is

$$\begin{aligned} & \frac{D(x, y; \sigma)}{\langle \Phi_{G.S.} | \Phi_{G.S.} \rangle} \\ &= \frac{\vec{F}^T \mathbf{T}_N \mathbf{T}_{N-1} \cdots \mathbf{T}_{j+1} \mathbf{N}_j^{(p)} \mathbf{T}_{j-1} \cdots \mathbf{T}_{i+1} \mathbf{N}_i^{(p)} \mathbf{T}_{i-1} \cdots \mathbf{T}_1 \vec{I}}{\vec{F}^T \mathbf{T}^N \vec{I}} \\ &= \frac{C_1 - C_2 \left(\frac{e_2}{e_1} \right)^i + C_3 \left(\frac{e_2}{e_1} \right)^j - C_4 \left(\frac{e_2}{e_1} \right)^{j-i} + C_5 \left(\frac{e_2}{e_1} \right)^{N-j+i} - C_6 \left(\frac{e_2}{e_1} \right)^{N-j} + C_7 \left(\frac{e_2}{e_1} \right)^{N-i} - C_8 \left(\frac{e_2}{e_1} \right)^N}{\frac{\omega_1^2}{2} \left\{ [(1 + 2\lambda_1^2)(1 + 2\lambda_2^2) + \omega_1] - [(1 + 2\lambda_1^2)(1 + 2\lambda_2^2) - \omega_1] \left(\frac{e_2}{e_1} \right)^N \right\}}, \end{aligned} \quad (4.32)$$

where

$$\begin{aligned} C_1 &= (e_1 - 2\lambda_1^2)(e_1 - 2\lambda_2^2)(\lambda_1^2 + \lambda_2^2 - e_1) \\ C_2 &= (e_1 - 2\lambda_2^2)(e_2 - 2\lambda_1^2)(\lambda_1^2 + \lambda_2^2 - e_1)(\lambda_2^2 e_1 + \lambda_1^2 e_2 - e_1 e_2) / e_2 \\ C_3 &= (e_1 - 2\lambda_1^2)(e_2 - 2\lambda_2^2)(\lambda_1^2 + \lambda_2^2 - e_2)(\lambda_2^2 e_1 + \lambda_1^2 e_2 - e_1 e_2) / e_2 \\ C_4 &= (e_1 - 2\lambda_1^2)(e_1 - 2\lambda_2^2)(\lambda_1^2 e_1 + \lambda_2^2 e_2 - e_1 e_2)(e_1 e_2 - \lambda_2^2 e_1 - \lambda_1^2 e_2) / (e_1 e_2) \\ C_5 &= (e_2 - 2\lambda_1^2)(e_2 - 2\lambda_2^2)(\lambda_2^2 e_1 + \lambda_1^2 e_2 - e_1 e_2)(e_1 e_2 - \lambda_1^2 e_1 - \lambda_2^2 e_2) / (e_1 e_2) \end{aligned}$$

$$\begin{aligned}
C_6 &= (e_1 - 2\lambda_1^2) (e_2 - 2\lambda_2^2) (\lambda_1^2 + \lambda_2^2 - e_1) (\lambda_1^2 e_1 + \lambda_2^2 e_2 - e_1 e_2) / e_1 \\
C_7 &= (e_1 - 2\lambda_1^2) (e_2 - 2\lambda_2^2) (\lambda_1^2 + \lambda_2^2 - e_2) (\lambda_1^2 e_1 + \lambda_2^2 e_2 - e_1 e_2) / e_1 \\
C_8 &= (e_2 - 2\lambda_1^2) (e_2 - 2\lambda_2^2) (\lambda_1^2 + \lambda_2^2 - e_2),
\end{aligned}$$

in the system size N . In the thermodynamic limit $N - j, i \rightarrow \infty$ keeping $|j - i|$ finite, we have

$$\frac{D(x, y; \sigma)}{\langle \Phi_{G.S.} | \Phi_{G.S.} \rangle} = \left[\frac{1}{2} \left(\frac{1}{\omega_1} + 1 \right) \right]^2 - \left(\frac{e_2}{e_1} \right)^{-|i-j|} \frac{\lambda_1^2 \lambda_2^2 [1 + 2(\lambda_1^2 + \lambda_2^2 + \lambda_1^4 + \lambda_2^4)]}{e_1^2 \omega_1^2}. \quad (4.33)$$

From (4.28), the first term in the right hand side cancels out with the last term in (3.31). We obtain

$$\langle n_i^p n_j^p \rangle - \langle n_i^p \rangle \langle n_j^p \rangle = - \left(\frac{e_2}{e_1} \right)^{-|i-j|} \frac{4\lambda_1^2 \lambda_2^2 [1 + 2(\lambda_1^2 + \lambda_2^2 + \lambda_1^4 + \lambda_2^4)]}{e_1^2 \omega_1^2}. \quad (4.34)$$

For the d -site, the similar calculation leads

$$\langle n_i^d n_j^d \rangle - \langle n_i^d \rangle \langle n_j^d \rangle = - \left(\frac{e_2}{e_1} \right)^{-|i-j|} \frac{4\lambda_1^2 \lambda_2^2}{(e_1 + e_2) \omega_1}. \quad (4.35)$$

The density correlation functions take negative value and decay exponentially with distance. We show the results in Figs. 19 and 20. For the parameter region (i) identified at the end of subsection IV A 4, the density correlation between p -sites is enhanced and that between d -sites is suppressed. For (ii) and (iii), they are suppressed.

Since we have no non-degenerate loop, the spin correlation functions $\langle S_i^z S_j^z \rangle$ are vanishing for $|j - i| \geq 2$. Since we have no self-closed bond at the sites where the adjacent cells are identified, $\langle b_{i,j}^\dagger b_{k,l} \rangle$ is vanishing for $|k - i| \geq 1$.

We evaluate the correlation function $\langle c_{i,\sigma}^p c_{j,\sigma}^{p\dagger} \rangle$. The geometric representation of the expectation value is (3.23), where an example of the graph $V \cup V'$ is shown in Fig. 15(e). We do not need the procedures shown in Figs. 5, because there is no site with four bonds. Therefore, we find $n(U_i \cup U_i') = 1$ in (3.15) and $m_j = 0$ in (3.24). In the representation, the operators modify the weight associated with the graph(s) which contains the cells between i and j . Let the transfer matrix associated with the operator $c_{i,\sigma}^p$ ($c_{j,\sigma}^{p\dagger}$) be $\mathbf{G}_i^{R,(p)}$ ($\mathbf{G}_j^{L,(p)}$). We need a new matrix $\mathbf{G}_n$ for the n -th cell ($i + 1 \leq n \leq j - 1$). From these matrices the expectation value can be written

$$\langle c_{i,\sigma}^p c_{j,\sigma}^{p\dagger} \rangle = \vec{F}^T \mathbf{T}_N \cdots \mathbf{T}_{j+1} \mathbf{G}_j^{L,(p)} \mathbf{G}_{j-1} \cdots \mathbf{G}_{i+1} \mathbf{G}_i^{R,(p)} \mathbf{T}_{i-1} \cdots \mathbf{T}_1 \vec{I}. \quad (4.36)$$

We derive the matrices. We first consider the matrix $\mathbf{G}_n$. It is reduced to a number, because we have only one kind of graph (a line) on the n -th cell ($i + 1 \leq n \leq j - 1$) (Fig. 21(a)). Let G_n be the quantity defined by a sum. The sum is taken over $V \cup V'$ on the lattice Λ_n such that the graph consists of loops shown in Fig. 16 on the k -th cell ($1 \leq k \leq i - 1$) and the line shown in Fig. 21(a) on the n -th cell ($i \leq n \leq j$). A line with $2n$ bonds is on n cells, since a cell has two valence bonds. The weight for the line is $(-1)^n$. We assign -1 to each n cells. In this way, the weight (3.22) is automatically taken into account. They are represented diagrammatically

$$\begin{aligned}
G_n &= \\
&= \\
&= -\lambda_1 \lambda_2 G_{n-1}.
\end{aligned} \quad (4.37)$$

We have

$$\mathbf{G}_n = -\lambda_1 \lambda_2. \quad (4.38)$$

For the matrix $\mathbf{G}_i^{(p)}$, let $G_i^{R,(p)}$ be the quantity defined by a sum. The sum is taken over $V \cup V'$ on the lattice Λ_i such that the graph consists of loops shown in Fig. 16 on the k -th cell ($1 \leq k \leq i-1$) and the graph shown in Fig. 21(b) or (c) on the i -th cell. The recursion relation is

$$\begin{aligned} G_i^{(p)} &= \\ &= \\ &= \lambda_1 A_{i-1} + \lambda_1 B_{i-1} + \lambda_1 \lambda_2^2 A_{i-1}, \end{aligned} \quad (4.39)$$

and is written

$$G_i^{(p)} = \mathbf{G}_i^{R,(p)} \begin{pmatrix} A_{j-1} \\ B_{j-1} \end{pmatrix}, \quad \mathbf{G}_i^{R,(p)} = \begin{pmatrix} \lambda_1 + \lambda_1 \lambda_2^2 & \lambda_1 \end{pmatrix}, \quad (4.40)$$

For $\mathbf{G}_j^{L,(p)}$, let $A_j^{(p)}$ and $B_j^{(p)}$ be the quantity defined by the right-hand side of (3.23) on the lattice Λ_j . The sum is taken over the graph $V \cup V'$ such that the graph consists of loops shown in Fig. 16 on the k -th cell ($1 \leq k \leq i-1$) and the graph shown in Fig. 21(a) on the l -th cell ($i \leq l \leq j$). The restriction for the sum is that the j -th cell is represented by either Fig. 21(d) for $A_j^{(p)}$ and (e) for $B_j^{(p)}$. The recursion relations are

$$\begin{aligned} A_j^{(p)} &= \\ &= \lambda_2 G_{j-1} \end{aligned} \quad (4.41)$$

$$\begin{aligned} B_j^{(p)} &= \\ &= \lambda_1^2 \lambda_2 G_{j-1}, \end{aligned} \quad (4.42)$$

and are written

$$\begin{pmatrix} A_j^{(p)} \\ B_j^{(p)} \end{pmatrix} = \mathbf{G}_j^{L,(p)} G_{j-1}, \quad \mathbf{G}_j^{L,(p)} = \begin{pmatrix} \lambda_2 \\ \lambda_1^2 \lambda_2 \end{pmatrix}, \quad (4.43)$$

From (4.19), (4.36), (4.38), (4.40), and (4.43), we obtain

$$\begin{aligned} \langle c_{i,\sigma}^p c_{j,\sigma}^{p\dagger} \rangle &= \frac{\vec{F}^T \mathbf{T}^{N-j} \mathbf{G}_j^{L,(p)} \mathbf{G}_i^{j-i-1} \mathbf{G}_i^{R,(p)} \mathbf{T}^{i-1} \vec{I}}{\vec{F}^T \mathbf{T}^N \vec{I}} \\ &= -(-\lambda_1 \lambda_2)^{j-i} \frac{C_1 \left(\frac{1}{e_1}\right)^{j-i-1} - C_2 \left(\frac{e_2}{e_1}\right)^{i-1} - C_3 \left(\frac{e_2}{e_1}\right)^{N-j} + C_4 \left(\frac{e_2}{e_1}\right)^N}{\omega_1 \left\{ [(1+2\lambda_1^2)(1+2\lambda_2^2) + \omega_1] - [(1+2\lambda_1^2)(1+2\lambda_2^2) - \omega_1] \left(\frac{e_2}{e_1}\right)^N \right\}}, \end{aligned} \quad (4.44)$$

where

$$\begin{aligned} C_1 &= (e_1 - 2\lambda_1^2) (e_1 - \lambda_1^2) (e_1 - 2\lambda_2^2) (e_1 - \lambda_2^2) / e_1 \\ C_2 &= (e_1 - \lambda_1^2) (e_1 - 2\lambda_2^2) (e_2 - 2\lambda_1^2) (e_2 - \lambda_2^2) / e_1^{j-i+1} \\ C_3 &= (e_1 - 2\lambda_1^2) (e_1 - \lambda_2^2) (e_2 - \lambda_1^2) (e_2 - 2\lambda_2^2) / e_1^{j-i+1} \\ C_4 &= (e_1 - 2\lambda_1^2) (e_1 - \lambda_1^2) (e_1 - 2\lambda_2^2) (e_1 - \lambda_2^2) / e_2^{j-i+1}, \end{aligned}$$

in the system size N . In the thermodynamic limit $N-j, i \rightarrow \infty$ keeping $|j-i|$ finite, we obtain

$$\langle c_{i,\sigma}^p c_{j,\sigma}^{p\dagger} \rangle = - \left(-\frac{\lambda_1 \lambda_2}{e_1} \right)^{-|i-j|} \frac{(2\lambda_1^2 + 1 + \omega_1)(2\lambda_2^2 + 1 + \omega_1)}{4e_1 \omega_1}. \quad (4.45)$$

Next, we evaluate the correlation function $\langle c_{i,\sigma}^d c_{j,\sigma}^{d\dagger} \rangle$. We show an example of the graph $V \cup V'$ in Fig. 15(f). (We have only one kind of the line.) Using the graph of the ends of the line (Figs. 21(f) and (g)) the matrices in (4.36) are

$$\mathbf{G}_i^{R,(d)} = \begin{pmatrix} -\lambda_1 \lambda_2 & 0 \end{pmatrix}, \quad \mathbf{G}_j^{L,(d)} = \begin{pmatrix} 1 \\ 2\lambda_1^2 \end{pmatrix}, \quad (4.46)$$

From these matrices we obtain

$$\langle c_{i,\sigma}^d c_{j,\sigma}^{d\dagger} \rangle = \frac{1}{\omega_1} \left(-\frac{\lambda_1 \lambda_2}{e_1} \right)^{-|i-j|}. \quad (4.47)$$

The correlation functions decay exponentially with the oscillating sign.

For a finite lattice under open boundary condition, the system is not translational invariant. In the thermodynamic limit, however, by the Fourier transformation of the correlation function $\langle c_{i,\sigma} c_{j,\sigma}^\dagger \rangle$, we obtain the momentum distribution function [6] for $\alpha = p, d$

$$\langle n_{k,\sigma}^\alpha \rangle = f^{(\alpha)} F(k, r) + f_0^{(\alpha)}, \quad (4.48)$$

where $f_0^{(\alpha)} = \langle n_{i,\sigma}^\alpha \rangle$ and

$$F(k, r) = \frac{2r[\cos k - r]}{1 + r^2 - 2r \cos k}, \quad (4.49)$$

where $f^{(p)} = -(\lambda_1^2 + 1 + \omega_1)(2\lambda_2^2 + 1 + \omega_1)/4e_1\omega_1$, $f^{(d)} = 1/\omega_1$, and $r = -\lambda_1\lambda_2/e_1$. The results are shown in Figs. 22 and 23. There is no singularity in $\langle n_{k,\sigma}^\alpha \rangle$. For the parameter range (i) in subsection IV A 4, the momentum distribution for the d -site is completely flat, while that for the p -site has a broad peak around $k = 0$. For (ii), the momentum distribution for the p -site is almost unity for every k and is completely flat, while that for the d -site is almost zero. For (iii), both of them are completely flat.

6. Discussion

All the correlation functions under consideration decay exponentially with distance. These results suggest the existence of a finite excitation gap. Therefore, it is expected that the state does not exhibit a metallic state but rather an insulating one. The correlation lengths are given by $\xi_{nn} = \left[\ln \left(\frac{e_2}{e_1} \right) \right]^{-1}$ for the density correlation functions and $\xi_{cc} = \left[\ln \left(\frac{\lambda_1 \lambda_2}{e_1} \right) \right]^{-1}$ for the correlation functions $\langle c_{i,\sigma}^\alpha c_{j,\sigma}^{\beta\dagger} \rangle$ (Fig. 24). The correlation lengths of the correlation between p -sites and that between d -sites are the same. The spin correlation functions vanish for $|j - i| \geq 2$. The singlet-pair correlation functions vanish for any $|j - i|$.

We consider the limit $|\lambda_1|, |\lambda_2| \ll 1$ ($\lambda_1 = \lambda_2$). We obtain $\xi_{nn}, \xi_{cc} = 0$. The density correlation functions for the nearest neighbor sites vanish. The ground state is described by a collection of the decoupled p -sites which are doubly occupied.

We consider the limit $\lambda_1, \lambda_2 \gg 1$ ($\lambda_1 = \lambda_2$). The correlation length converges to a finite value: $\xi_{nn} = \left[\ln \left(\frac{2-\sqrt{2}}{2+\sqrt{2}} \right) \right]^{-1}$ and $\xi_{cc} = \left[\ln \left(\frac{1}{4+2\sqrt{2}} \right) \right]^{-1}$. The density correlation function for the nearest neighbor p -sites remains finite, while that for the nearest neighbor d -sites vanish. Since there is almost one electron per a site, the correlation between d -sites is suppressed and that between p -sites is enhanced.

For $|\lambda_1| \ll 1, \lambda_2 \gg 1$, the correlations are suppressed. This is due to that the system decouples to a collection of the pairs of p - and d -sites.

The ground state (4.3) is a half-filling state. In the non-interacting system, the filling factor corresponds to that of a metallic state at $2\lambda_1\lambda_2 - 1 = 0$ and that of a band insulator for $2\lambda_1\lambda_2 - 1 \neq 0$.

Therefore, we have a metal-insulator transition when λ_1, λ_2 are fixed to satisfy $2\lambda_1\lambda_2 - 1 = 0$, and the on-site Coulomb interaction U on d -sites is varied from 0 to ∞ . In the non-interacting system, the correlation length, which is proportional to the inverse of the energy gap, takes a finite value for $|\lambda_1|, |\lambda_2| \ll 1$, it diverges when $2\lambda_1\lambda_2 - 1 = 0$ hold, and it goes to zero for $\lambda_1, \lambda_2 \gg 1$. These properties are completely different from that of the ground state (4.3).

B. Notation of the transfer matrices

In order to present the calculations in latter models efficiently we fix some notations. From the derivation in subsection (IV A 3), the norm of the ground state can be generally written

$$\langle \Phi_{G.S.} | \Phi_{G.S.} \rangle = \vec{F}^T \mathbf{T}_N \cdots \mathbf{T}_2 \mathbf{T}_1 \vec{I}, \quad (4.50)$$

where the matrices depend on the model under consideration.

We describe the expectation value of a local operator $\mathcal{O}_i$ by using the transfer matrices. In the geometric representation, when there is an operator $\mathcal{O}_i$, the weight associated with the graph which contains the i -th cell is modified. Therefore, we replace the transfer matrix $\mathbf{T}_i$ by $\mathbf{O}_i$ which is a matrix associated with the operator $\mathcal{O}_i$. The expectation value is written

$$\langle \Phi_{G.S.} | \mathcal{O}_i | \Phi_{G.S.} \rangle = \vec{F}^T \mathbf{T}_N \cdots \mathbf{T}_{i+1} \mathbf{O}_i \mathbf{T}_{i-1} \cdots \mathbf{T}_1 \vec{I}. \quad (4.51)$$

When $\mathcal{O}_i$ is the number operator $n_{i,\sigma}^\alpha$ where $\alpha = d(p)$ for a $p(d)$ -site, let the corresponding matrix be

$$\mathbf{O}_i = \mathbf{N}_i^{(\alpha)}. \quad (4.52)$$

For the two-point correlation function $\langle \mathcal{O}_i^R \mathcal{O}_j^L \rangle$, the weight associated with the graph which contains the cells between i and j is modified. Let $\mathbf{P}_k$ be the transfer matrix between the sites $i+1$ and $j-1$, and $\mathbf{O}_i^R$ ($\mathbf{O}_j^L$) be the matrix associated with the operator $\mathcal{O}_i^R$ ($\mathcal{O}_j^L$). We have

$$\langle \Phi_{G.S.} | \mathcal{O}_i^R \mathcal{O}_j^L | \Phi_{G.S.} \rangle = \vec{F}^T \mathbf{T}_N \mathbf{T}_{N-1} \cdots \mathbf{T}_{j+1} \mathbf{O}_j^L \mathbf{P}_{j-1} \cdots \mathbf{P}_{i+1} \mathbf{O}_i^R \mathbf{T}_{i-1} \cdots \mathbf{T}_1 \vec{I}. \quad (4.53)$$

We use the following notations:

$$\begin{aligned} \mathbf{P}_k &= \mathbf{T}_k, \quad \mathbf{O}_i^R = \mathbf{N}_i^{(\alpha)}, \quad \mathbf{O}_j^L = \mathbf{N}_j^{(\alpha)} && \text{for the quantity } D(i, j; \sigma) \text{ in (3.32)} \\ \mathbf{P}_k &= \mathbf{S}_k, \quad \mathbf{O}_i^R = \mathbf{S}_i^{R,(\alpha)}, \quad \mathbf{O}_j^L = \mathbf{S}_j^{L,(\alpha)} && \text{for the spin correlation function} \\ \mathbf{P}_k &= \mathbf{H}_k, \quad \mathbf{O}_i^R = \mathbf{H}_i^{R,(\gamma)}, \quad \mathbf{O}_j^L = \mathbf{H}_j^{L,(\gamma)} && \text{for the singlet-pair correlation function} \\ \mathbf{P}_k &= \mathbf{G}_k, \quad \mathbf{O}_i^R = \mathbf{G}_i^{R,(\alpha)}, \quad \mathbf{O}_j^L = \mathbf{G}_j^{L,(\alpha)} && \text{for the correlation function } \langle c_{i,\sigma} c_{j,\sigma}^\dagger \rangle. \end{aligned} \quad (4.54)$$

For the singlet-pair correlation function $\langle b_{i,j}^\dagger b_{k,l} \rangle$, we distinguish the following four cases by γ :

$$\left\{ \begin{array}{ll} \text{(i)} & \gamma=p \quad \text{sites } i \text{ and } j \text{ are } p\text{-sites and } i=j; \\ \text{(ii)} & \gamma=pp \quad \text{sites } i \text{ and } j \text{ are } p\text{-sites and } i \neq j; \\ \text{(iii)} & \gamma=pd \quad \text{site } i \text{ is } p\text{-site and site } j \text{ is } d\text{-site}; \\ \text{(iv)} & \gamma=dd \quad \text{sites } i \text{ and } j \text{ are } d\text{-sites.} \end{array} \right. \quad (4.55)$$

We can evaluate multi-point correlation functions for operators which are constructed from fermion operators. The numerator of the correlation function is obtained by an insertion of the transfer matrices which are associated with the operators.

C. Model B

1. Hamiltonian

Model B is constructed from a cell with two p -sites and one d -site (Fig. 25(a)). This is one of the models of Strack [3] which was studied by Bares and Lee [6]. The cell Hamiltonian (2.2) is obtained by choosing $\alpha_{n,\sigma}^{(B)} = \sum_{r=1}^3 \lambda_r c_{r,\sigma} \equiv \lambda_1 c_{1,\sigma}^p + \lambda_2 c_{2,\sigma}^p + \lambda_3 c_{3,\sigma}^d$ in (2.3) and setting $\lambda_3 = 1$ without loss of generality (see Fig. 25(a) for intra-cell index). The full Hamiltonian is obtained by identifying site 1 in the $(n-1)$ -th cell with site 2 in the n -th cell (Fig. 25(b)). The Hamiltonian is

$$H_S = \mathcal{P} \sum_{\sigma=\uparrow,\downarrow} \left\{ \sum_{n=1}^N \left[(-\lambda_1 \lambda_2 c_{n+1,\sigma}^p \dagger c_{n,\sigma}^p - \lambda_1 c_{n+1,\sigma}^p \dagger c_{n,\sigma}^d - \lambda_2 c_{n,\sigma}^p \dagger c_{n,\sigma}^d + h.c.) \right. \right. \\ \left. \left. + \epsilon_n^p c_{n,\sigma}^p \dagger c_{n,\sigma}^p + \epsilon_n^d c_{n,\sigma}^d \dagger c_{n,\sigma}^d \right] + \epsilon_{N+1}^p c_{N+1,\sigma}^p \dagger c_{N+1,\sigma}^p \right\} \mathcal{P}, \quad (4.56)$$

where the on-site potentials are $\epsilon_1^p = -\lambda_2^2$, $\epsilon_n^p = -(\lambda_1^2 + \lambda_2^2)$ ($2 \leq n \leq N$), $\epsilon_{N+1}^p = -\lambda_1^2$, and $\epsilon^d = -2$. A unit cell is labeled by n . The ground state is

$$\begin{aligned} |\Phi_{G.S.}^B\rangle &= \mathcal{P} \prod_{n=1}^N \prod_{\sigma=\uparrow,\downarrow} \alpha_{n,\sigma}^{(B)\dagger} |0\rangle \\ &= \mathcal{P} \prod_{n=1}^N \prod_{\sigma=\uparrow,\downarrow} \left(\lambda_1 c_{n,\sigma}^p \dagger + \lambda_2 c_{n+1,\sigma}^p \dagger + c_{n,\sigma}^d \dagger \right) |0\rangle, \end{aligned} \quad (4.57)$$

which is a half-filled state. In the parameter space, $\lambda_2 = -\lambda_1$, this model reduces one of the models in Ref. [3]. The model in Ref. [6] is recovered by setting $\lambda_1 = -\lambda_2 = \tilde{V}^{-1}$.

2. Band structure in the single-electron problem

We investigate the single-electron problem for the Hamiltonian (4.56). We consider the system with an even number of unit cells under the periodic boundary condition. The similar calculation to that in Sec. IV A 2 leads to the dispersion relations

$$E_{\pm} = -\frac{1}{2} \left[2\lambda_1 \lambda_2 \cos k + \lambda_1^2 + \lambda_2^2 + 2 \mp \sqrt{(2\lambda_1 \lambda_2 \cos k + \lambda_1^2 + \lambda_2^2)^2 + 4} \right], \quad (4.58)$$

where $-$, $+$ are the band index with $-$ (*resp.* $+$) corresponding to the $+$ (*resp.* $-$) sign, and k is the wave vector with (4.6). The energy gap between two bands is $\Delta = \frac{1}{2} \sqrt{(\lambda_1 + \lambda_2)^4 + 4} + \frac{1}{2} \sqrt{(\lambda_1 - \lambda_2)^4 + 4} - 2\lambda_1 \lambda_2$, which is nonvanishing for any finite λ_1, λ_2 .

The electron number in the ground state (4.57) corresponds to full-filling of the lower band. Therefore, the ground state of the non-interacting system is insulating.

3. Correlation functions

From (4.50), the norm of the ground state is

$$\langle \Phi_{G.S.}^B | \Phi_{G.S.}^B \rangle = \frac{e_1^N}{c_1} (R_{11} L_{11} + 2R_{21} L_{21} + R_{31} L_{31}), \quad (4.59)$$

where the corresponding matrices in (4.14), (4.16), and (4.18) are

$$\mathbf{T}_n = \begin{pmatrix} 2\lambda_2^2 + \lambda_2^4 & 2\lambda_2^2 & 0 \\ \lambda_1^2 + \lambda_1^2\lambda_2^2 & 2\lambda_1^2 + \lambda_1^2\lambda_2^2 & \lambda_1^2 \\ \lambda_1^4 & 2\lambda_1^4 & \lambda_1^4 \end{pmatrix}, \quad \vec{I} = \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix}, \quad \vec{F} = \begin{pmatrix} 1 \\ 2 \\ 1 \end{pmatrix},$$

$$\mathbf{D} = \begin{pmatrix} e_1 & 0 & 0 \\ 0 & e_2 & 0 \\ 0 & 0 & e_3 \end{pmatrix}, \quad \text{and} \quad \mathbf{C} = \begin{pmatrix} c_1 & 0 & 0 \\ 0 & c_2 & 0 \\ 0 & 0 & c_3 \end{pmatrix}. \quad (4.60)$$

The matrix $\mathbf{T}_n$ and the initial and the final vectors are derived in Appendix G 1. Here e_i ($i = 1, 2$, and 3) are the eigenvalues of $\mathbf{T}_n$

$$e_1 = \frac{s}{3} + \frac{1}{3} \left(p^{\frac{1}{3}} - tp^{\frac{1}{3}} \right)$$

$$e_2 = \frac{s}{3} - \frac{1}{6} \left[\left(p^{\frac{1}{3}} - tp^{\frac{1}{3}} \right) + i\sqrt{3} \left(p^{\frac{1}{3}} + tp^{\frac{1}{3}} \right) \right]$$

$$e_3 = \frac{s}{3} - \frac{1}{6} \left[\left(p^{\frac{1}{3}} - tp^{\frac{1}{3}} \right) - i\sqrt{3} \left(p^{\frac{1}{3}} + tp^{\frac{1}{3}} \right) \right],$$

where $s = 2\lambda_1 + 2\lambda_2 + \lambda_1^2 + \lambda_1\lambda_2 + \lambda_2^2$, $t = -4\lambda_1^2 - 2\lambda_1\lambda_2 - 4\lambda_2^2 - 4\lambda_1^3 - 2\lambda_1^2\lambda_2 - 2\lambda_1\lambda_2^2 - 4\lambda_2^3 - \lambda_1^4 + \lambda_1^3\lambda_2 + \lambda_1\lambda_2^3 - \lambda_2^4$, and $p = (p_1 + 3^{\frac{3}{2}}\sqrt{p_2})/2$. Here $p_1 = 16\lambda_1^3 + 12\lambda_1^2\lambda_2 + 12\lambda_1\lambda_2^2 + 16\lambda_2^3 + 24\lambda_1^4 + 18\lambda_1^3\lambda_2 + 6\lambda_1^2\lambda_2^2 + 18\lambda_1\lambda_2^3 + 24\lambda_2^4 + 12\lambda_1^5 - 12\lambda_1^3\lambda_2^2 - 12\lambda_1^2\lambda_2^3 + 12\lambda_2^5 + 2\lambda_1^6 - 3\lambda_1^5\lambda_2 + 14\lambda_1^3\lambda_2^3 - 3\lambda_1\lambda_2^5 + 2\lambda_2^6$ and $p_2 = \lambda_1^2\lambda_2^2(-16\lambda_1^2 - 16\lambda_2^2 - 48\lambda_1^3 - 32\lambda_1^2\lambda_2 - 32\lambda_1\lambda_2^2 - 48\lambda_2^3 - 68\lambda_1^4 - 72\lambda_1^3\lambda_2 - 60\lambda_1^2\lambda_2^2 - 72\lambda_1\lambda_2^3 - 68\lambda_2^4 - 56\lambda_1^5 - 40\lambda_1^4\lambda_2 - 32\lambda_1^3\lambda_2^2 - 32\lambda_1^2\lambda_2^3 - 40\lambda_1\lambda_2^4 - 56\lambda_2^5 - 28\lambda_1^6 + 12\lambda_1^5\lambda_2 + 12\lambda_1^4\lambda_2^2 + 8\lambda_1^3\lambda_2^3 + 12\lambda_1^2\lambda_2^4 + 12\lambda_1\lambda_2^5 - 28\lambda_2^6 - 8\lambda_1^7 + 16\lambda_1^6\lambda_2 - 8\lambda_1^4\lambda_2^3 - 8\lambda_1^3\lambda_2^4 + 16\lambda_1\lambda_2^6 - 8\lambda_2^7 - \lambda_1^8 + 4\lambda_1^7\lambda_2 - 4\lambda_1^6\lambda_2^2 - 4\lambda_1^5\lambda_2^3 + 10\lambda_1^4\lambda_2^4 - 4\lambda_1^3\lambda_2^5 - 4\lambda_1^2\lambda_2^6 + 4\lambda_1\lambda_2^7 - \lambda_2^8)$. They satisfy $e_1 > e_2 > e_3 > 0$ for $\lambda_1 \neq 0$ and $\lambda_2 \neq 0$. The matrix $\mathbf{L} = (L_{ij})$ ($\mathbf{R} = (R_{ij})$) is constructed from the left(right) eigenvectors. We choose the left eigenvectors $\vec{L}_1 = (L_{11}, L_{12}, L_{13})^T$, $\vec{L}_2 = (L_{21}, L_{22}, L_{23})^T$, and $\vec{L}_3 = (L_{31}, L_{32}, L_{33})^T$ corresponding to the eigenvalues e_1 , e_2 , and e_3 , respectively, where $L_{j1} = \lambda_1^2(\lambda_1^4 - e_j)(1 + \lambda_2^2) - \lambda_1^6$, $L_{j2} = (\lambda_1^4 - e_j)(2\lambda_2^2 - \lambda_2^4 - e_j)$, and $L_{j3} = \lambda_1^2(2\lambda_2^2 - \lambda_2^4 - e_j)$. We choose the right eigenvectors $\vec{R}_1 = (R_{11}, R_{21}, R_{31})^T$, $\vec{R}_2 = (R_{12}, R_{22}, R_{32})^T$, and $\vec{R}_3 = (R_{13}, R_{23}, R_{33})^T$, where $R_{1j} = 2\lambda_2^2(\lambda_1^4 - e_j)$, $R_{2j} = (\lambda_1^4 - e_j)(e_j - 2\lambda_2^2 - \lambda_2^4)$, and $R_{3j} = 2\lambda_1^4(\lambda_2^2 + \lambda_2^4 - e_j)$.

We evaluate the expectation value of the number operator $\langle n_{i,\sigma}^\alpha \rangle$. The transfer matrices associated with $n_{i,\sigma}^\alpha$ are

$$\mathbf{N}_i^{(p)} = \begin{pmatrix} \lambda_2^2 + \lambda_2^4 & 2\lambda_2^2 & 0 \\ \frac{1}{2}\lambda_1^2\lambda_2^2 & \lambda_1^2 + \lambda_1^2\lambda_2^2 & \lambda_1^2 \\ 0 & \lambda_1^4 & 0 \end{pmatrix}, \quad \mathbf{N}_i^{(d)} = \begin{pmatrix} \lambda_2^2 & \lambda_2^2 & 0 \\ \frac{1}{2}\lambda_1^2 & \lambda_1^2 & \frac{1}{2}\lambda_1^2 \\ 0 & 0 & 0 \end{pmatrix}. \quad (4.61)$$

They are derived in Appendix G 2. From (4.27), (4.59), (4.60), and (4.61), we obtain

$$\langle n_{i,\sigma}^\alpha \rangle = \begin{cases} \left(L_{11} - \frac{1}{2}\lambda_1 L_{12} \right) \lambda_2 R_{11} + (L_{12} - L_{13})R_{21} + L_{13}R_{31} & \text{for } \alpha = p; \\ (\lambda_2 L_{11} + \frac{1}{2}\lambda_1 L_{12})R_{11} + (\lambda_2 L_{11} + \lambda_1 L_{12})R_{21} + \frac{1}{2}\lambda_1 L_{12}R_{31} & \text{for } \alpha = d, \end{cases} \quad (4.62)$$

in the thermodynamic limit, $N, i, N-i \rightarrow \infty$. It can be verified that there are two electrons per a unit cell as $\langle n_i^p \rangle + \langle n_i^d \rangle = 2$. The results are shown in Figs. 27. The case $\lambda_2 = |\lambda_1|$ was discussed in Ref. [6]. We consider the case $|\lambda_1| \ll 1$, $\lambda_2 \gg 1$. The occupation on p - (d -) site have a minimum (maximum) at a intermediate value of λ_1 .

From (3.31), (4.27), (4.32), (4.59), (4.60), and (4.61), the density correlation functions are

$$\langle n_i^\alpha n_j^\alpha \rangle - \langle n_i^\alpha \rangle \langle n_j^\alpha \rangle = \left(\frac{e_2}{e_1} \right)^{-|i-j|} \frac{1}{e_1 e_2 c_1 c_2} R_2^{(\alpha)} L_2^{(\alpha)} + \left(\frac{e_3}{e_1} \right)^{-|i-j|} \frac{1}{e_1 e_3 c_1 c_3} R_3^{(\alpha)} L_3^{(\alpha)}, \quad (4.63)$$

where

$$\begin{aligned}
R_j^{(p)} &= (L_{11} - L_{12}/2) R_{1j} + (L_{12} - L_{13}) R_{2j} + L_{13} R_{3j} \\
L_j^{(p)} &= R_{11} L_{j1} + (-R_{11}/2 + R_{21}) L_{j2} + (-R_{21} + R_{31}) L_{j3} \\
R_j^{(d)} &= (\lambda_2 L_{11} + \lambda_1 L_{12}/2) R_{1j} + (\lambda_2 L_{11} + \lambda_1 L_{12}) R_{2j} + \lambda_1 L_{12} R_{3j}/2 \\
L_j^{(d)} &= \lambda_2 (R_{11} + R_{21}) L_{21} + \lambda_1 (R_{11}/2 + R_{21} + R_{31}) L_{22},
\end{aligned}$$

in the thermodynamic limit $N - j, i \rightarrow \infty$ keeping $|j - i|$ finite. The density correlation functions take negative value and decay exponentially with distance. We show the results in Figs. 28 and 29. For $|\lambda_1| \ll 1, \lambda_2 \gg 1$, the density correlations are suppressed. They have a minimum at a intermediate value of λ_1 .

We evaluate the spin correlation function. The transfer matrices are

$$\begin{aligned}
\mathbf{S}_n &= \lambda_1^2 \lambda_2^2, \\
\mathbf{S}_i^{R,(p)} &= \left(\frac{1}{2} \lambda_1^2 \lambda_2^2, 0, 0 \right), \quad \mathbf{S}_j^{L,(p)} = \begin{pmatrix} 0 \\ -\lambda_1^2 \\ -\lambda_1^4 \end{pmatrix}, \\
\mathbf{S}_i^{R,(d)} &= \left(\frac{1}{2} \lambda_1^2, \lambda_1^2, \frac{1}{2} \lambda_1^2 \right), \quad \mathbf{S}_j^{L,(d)} = \begin{pmatrix} -\lambda_2^2 \\ 0 \\ 0 \end{pmatrix}.
\end{aligned} \tag{4.64}$$

They are derived in Appendix G 3. From (4.53), (4.54), (4.59), and (4.64), we have

$$\begin{aligned}
&\langle S_i^z S_j^z \rangle \\
&= \frac{\vec{F}^T \mathbf{T}^{N-j} \mathbf{S}_j^{L,(\alpha)} \mathbf{S}_i^{R,(\beta)} \mathbf{T}^{i-1} \vec{I}}{\vec{F}^T \mathbf{T}^N \vec{I}} \\
&= \left(\frac{\lambda_1^2 \lambda_2^2}{e_1} \right)^{-|i-j|} \times \begin{cases} -\frac{\lambda_1^2}{2e_1 c_1} (L_{12} + \lambda_1^2 L_{13}) R_{11} & \text{for } \beta = p \text{ and } \alpha = p \\ -\frac{1}{2e_1 c_1} L_{11} (R_{11} + 2R_{21} + R_{31}) & \text{for } \beta = d \text{ and } \alpha = d \\ -\frac{\lambda_1^2}{2\lambda_2^2 e_1 c_1} (L_{12} + \lambda_1^2 L_{13}) (R_{11} + 2R_{21} + R_{31}) & \text{for } \beta = p \text{ and } \alpha = d \\ -\frac{\lambda_2^2}{2e_1 c_1} (L_{11} R_{11}) & \text{for } \beta = d \text{ and } \alpha = p. \end{cases}
\end{aligned} \tag{4.65}$$

We note that $\langle S_{x+1}^{z,p} S_x^{z,d} \rangle \neq \langle S_x^{z,p} S_x^{z,d} \rangle$, because the Hamiltonian is not invariant under the reflection of the lattice. All the spin correlation functions take negative value and decay exponentially with distance. We show the results in Figs. 30. For $|\lambda_1| \ll 1, \lambda_2 \gg 1$, the spin correlations are suppressed.

We evaluate the singlet-pair correlation function (3.38) where i and j (k and l) are in the same cell. For (4.55)-(ii), the correlation function is vanishing. We evaluate them for (4.55)-(i) and (iii). (The position of the operators are shown in Fig. 43(g) and (h) in Appendix G 4, where a double solid (broken) line represents the operator $b_{i,j}^\dagger$ ($b_{k,l}$)). The transfer matrices are

$$\begin{aligned}
\mathbf{H}_n &= 2 \\
\mathbf{H}_i^{R,(pp)} &= \lambda_1^2 \lambda_2^2 \begin{pmatrix} 1, 0, 0 \end{pmatrix}, \quad \mathbf{H}_k^{L,(pp)} = \begin{pmatrix} 0 \\ 2\lambda_1^2 \\ 2\lambda_1^4 \end{pmatrix} \\
\mathbf{H}_i^{R,(dp)} &= 2\lambda_1^2 \lambda_2 \begin{pmatrix} 1, 1, 0 \end{pmatrix}, \quad \mathbf{H}_k^{L,(dp)} = \begin{pmatrix} 0 \\ 2\lambda_1 \lambda_2^2 \\ 0 \end{pmatrix}.
\end{aligned} \tag{4.67}$$

They are derived in Appendix G 4. From (4.53), (4.54), (4.59), and (4.67), we obtain

$$\langle b_{i,j}^\dagger b_{k,l} \rangle = \frac{\vec{F}^T \mathbf{T}^{N-k} \mathbf{H}_k^{L,(\gamma)} \mathbf{H}_i^{R,(\gamma)} \mathbf{T}^{i-1} \vec{I}}{\vec{F}^T \mathbf{T}^N \vec{I}} \tag{4.68}$$

$$= \left(\frac{\lambda_1^2 \lambda_2^2}{e_1} \right)^{-|i-k|} \times \begin{cases} L_{13} R_{11} & \text{for } \gamma = p \\ \frac{4\lambda_1 \lambda_2}{e_1 c_1} L_{12} (R_{11} + R_{21}) & \text{for } \gamma = dp. \end{cases} \tag{4.69}$$

The singlet-pair correlation function decay exponentially with distance. The results are shown in Fig. 31 for $\gamma = p$. For $|\lambda_1| \ll 1$, $\lambda_2 \gg 1$, the singlet-pair correlations are suppressed.

We evaluate the correlation function $\langle c_{i,\sigma}^\alpha c_{j,\sigma}^{\alpha\dagger} \rangle$. The transfer matrices are

$$\begin{aligned} \mathbf{G}_n &= -\lambda_1 \lambda_2 \begin{pmatrix} 1 + \lambda_2^2 & 1 \\ \lambda_1^2 & \lambda_1^2 \end{pmatrix} \\ \mathbf{G}_i^{R,(p)} &= -\lambda_1 \lambda_2 \begin{pmatrix} 1 + \lambda_2^2 & 1 & 0 \\ \lambda_1^2 & \lambda_1^2 & 0 \end{pmatrix}, \quad \mathbf{G}_j^{L,(p)} = \begin{pmatrix} \lambda_2^2 & 0 \\ \lambda_1^2 + \frac{1}{2} \lambda_1^2 \lambda_2^2 & \lambda_1^2 \\ \lambda_1^4 & \lambda_1^4 \end{pmatrix} \\ \mathbf{G}_i^{R,(d)} &= -\lambda_1 \begin{pmatrix} \lambda_2^2 & \lambda_2^2 & 0 \\ \lambda_1^2 & 2\lambda_1^2 & \lambda_1^2 \end{pmatrix}, \quad \mathbf{G}_j^{L,(d)} = -\lambda_2 \begin{pmatrix} \lambda_2^2 & 0 \\ \frac{1}{2} \lambda_1^2 & \frac{1}{2} \lambda_1^2 \\ 0 & 0 \end{pmatrix}. \end{aligned} \quad (4.70)$$

They are derived in Appendix G 5. The matrix $\mathbf{G}_n$ is diagonalized

$$\mathbf{G}_n = -\lambda_1 \lambda_2 \tilde{\mathbf{R}} \tilde{\mathbf{D}} \tilde{\mathbf{C}}^{-1} \tilde{\mathbf{L}}, \quad (4.71)$$

where

$$\tilde{\mathbf{D}} = \begin{pmatrix} g_1 & 0 \\ 0 & g_2 \end{pmatrix}, \quad \tilde{\mathbf{R}} = \begin{pmatrix} \tilde{R}_{11} & \tilde{R}_{12} \\ \tilde{R}_{21} & \tilde{R}_{22} \end{pmatrix}, \quad \tilde{\mathbf{L}} = \begin{pmatrix} \tilde{L}_{11} & \tilde{L}_{12} \\ \tilde{L}_{21} & \tilde{L}_{22} \end{pmatrix}, \quad \tilde{\mathbf{C}} = \begin{pmatrix} \tilde{c}_1 & 0 \\ 0 & \tilde{c}_2 \end{pmatrix}. \quad (4.72)$$

Here g_k are the eigenvalues of $\mathbf{G}_n$, $g_1 = (1 + \lambda_1 + \lambda_2 + \omega_2)/2$ and $g_2 = (1 + \lambda_1 + \lambda_2 - \omega_2)/2$ with $\omega_2 = \sqrt{1 + 2(\lambda_1 + \lambda_2) + (\lambda_1 - \lambda_2)^2}$. They satisfy $g_1 > g_2 > 0$ for $\lambda_1 \neq 0$ and $\lambda_2 \neq 0$. We choose the left eigenvectors $\tilde{L}_1 = (\tilde{L}_{11}, \tilde{L}_{12})^T$ and $\tilde{L}_2 = (\tilde{L}_{21}, \tilde{L}_{22})^T$ corresponding to the eigenvalues g_1 and g_2 , respectively, where $\tilde{L}_{j1} = g_j - \lambda_1^2$, $\tilde{L}_{j2} = 1$, and the right eigenvectors $\tilde{R}_1 = (\tilde{R}_{11}, \tilde{R}_{21})^T$ and $\tilde{R}_2 = (\tilde{R}_{12}, \tilde{R}_{22})^T$ where $\tilde{R}_{1j} = g_j - \lambda_1^2$, $\tilde{R}_{2j} = \lambda_1^2$. Here $\tilde{\mathbf{C}} = \tilde{\mathbf{L}} \tilde{\mathbf{R}}$.

From these matrices and (4.44), we obtain

$$\langle c_{i,\sigma} c_{j,\sigma}^\dagger \rangle = \left(-\lambda_1 \lambda_2 \frac{g_1}{e_1} \right)^{-|i-j|} f_1^{(\alpha)} + \left(-\lambda_1 \lambda_2 \frac{g_2}{e_1} \right)^{-|i-j|} f_2^{(\alpha)}, \quad (4.73)$$

where

$$f_m^{(p)} = \frac{1}{c_1 \tilde{c}_m} \left[\frac{1}{2} (g_m - \lambda_1^2) L_{12} + \lambda_1^2 L_{13} \right] \left[(g_m - \lambda_1^2) R_{11} + R_{21} \right], \quad (4.74)$$

$$\begin{aligned} f_m^{(d)} &= \frac{1}{e_1 g_m c_1 \tilde{c}_m} \left[\lambda_2^2 (g_m - \lambda_1^2) L_{11} + \frac{1}{2} g_m \lambda_1^2 L_{12} \right] \\ &\quad \times \left[\lambda_2^2 (g_m - \lambda_1^2) (R_{11} + R_{21}) + \lambda_1^2 (R_{11} + 2R_{21} + R_{31}) \right]. \end{aligned} \quad (4.75)$$

The correlation functions decay exponentially.

By the Fourier transformation of the correlation function $\langle c_{i,\sigma} c_{j,\sigma}^\dagger \rangle$, we obtain the momentum distribution function for $\alpha = p$ and d

$$\langle n_{k,\sigma}^\alpha \rangle = f_1^{(\alpha)} F_1(k, r_1) + f_2^{(\alpha)} F_2(k, r_2) + f_0^{(\alpha)}, \quad (4.76)$$

where $f_0^{(\alpha)} = \langle n_{i,\sigma}^\alpha \rangle$ and

$$F_i(k, r_i) = \frac{2r_i [\cos k - r_i]}{1 + r_i^2 - 2r_i \cos k}. \quad (4.77)$$

where $r_i = -\lambda_1 \lambda_2 g_i / e_1$. The results are shown in Figs. 32 and 33. There is no singularity in $\langle n_{k,\sigma}^\alpha \rangle$. For $|\lambda_1| \ll 1$, $\lambda_2 \gg 1$, the momentum distributions for the p - and d -sites are flat.

4. Discussion

All the correlation functions under consideration decay exponentially with distance. These results suggest the existence of a finite excitation gap. The existence of the energy gap is numerically confirmed in Ref. [28]. Therefore, it is expected that the state is insulating. The correlation lengths are given by $\xi_{nn} = \left[\ln \left(\frac{e_2}{e_1} \right) \right]^{-1}$, $\xi_{ss} = \xi_{bb} = \left[\ln \left(\frac{\lambda_1^2 \lambda_2^2}{e_1} \right) \right]^{-1}$, for the spin and singlet-pair correlation functions, respectively, and $\xi_{cc} = \left[\ln \left(\frac{\lambda_1^2 \lambda_2^2 g_1}{e_1} \right) \right]^{-1}$ (Fig. 34). (They satisfy the relation $\xi_{cc} > \xi_{nn} > \xi_{ss} = \xi_{bb}$.) The correlation lengths of the correlation between p -sites and that between d -sites are same. We note that the spin correlation is ferromagnetic.

We consider the region $\lambda_1, \lambda_2 \gg 1$. The d -sites are almost empty and the p -sites are almost doubly occupied. The correlation lengths behave $\xi_{cc} \sim \lambda_1$ and $\xi_{nn}, \xi_{ss}, \xi_{bb} \sim \frac{\lambda_1}{2}$ (for $\lambda_1 = \lambda_2$). The correlation functions for the nearest neighbor sites are suppressed.

For $|\lambda_1|, |\lambda_2| \ll 1$, there is almost one electron per a site. The density correlation function for the nearest neighbor p -sites are enhanced, while that for d -sites are suppressed. The spin correlation function for the nearest neighbor p -sites are suppressed, and that for d -sites are enhanced. Therefore, the electrons on the d -sites have a tendency to behave like a localized spin. It corresponds to a kind of Kondo lattice regime [6] in the sense that there are one localized electron and one conduction electron per a unit cell. The ground state is described by a collection of local singlets between them. The effective exchange coupling between the p - and d -sites $J \sim \frac{\lambda_1 \lambda_2}{\epsilon^p - \epsilon^d}$ is comparable to the hopping amplitude between p -sites.

For $|\lambda_1| \ll 1, \lambda_2 \gg 1$, the correlations are suppressed. This is due to that the system decouples to a collection of the pairs of p - and d -sites.

The ground state (4.57) is a half-filling state. The filling factor corresponds to that of a band insulator in the non-interacting system where the excitation gap satisfies the relation $1 < \Delta < 2$. Therefore, the correlation length is finite and is almost independent on the parameters λ_1 and λ_2 , which is different from that of the ground state (4.57). The properties of the ground state (4.57) are completely different from that of the non-interacting system.

D. Model C

1. Hamiltonian

The lattice of Model C is constructed from a cell with four d -sites and one p -site (Fig. 35(a)). The model has four free parameters. We investigate the simplest model with one parameter. The cell Hamiltonian is obtained by choosing $\alpha_{n,\sigma}^{(C)} = \sum_{r=1}^5 \lambda_r c_{r,\sigma} \equiv \lambda_1 c_{1,\sigma}^d + \lambda_2 c_{2,\sigma}^d + \lambda_3 c_{3,\sigma}^d + \lambda_4 c_{4,\sigma}^d + \lambda_5 c_{5,\sigma}^p$ and setting $\lambda_r = 1$ ($r = 1, 2, 3, 4$) and $\lambda_5 = \lambda$ (see Fig. 35(a) for intra-cell index). The full Hamiltonian is obtained by identifying sites 1 and 2 in the $(n-1)$ -th cell with sites 3 and 4 in the n -th cell, respectively (Fig. 35(b)). The Hamiltonian is

$$\begin{aligned}
 H_S = \mathcal{P} \sum_{\sigma=\uparrow, \downarrow} \left\{ \sum_{n=1}^N \left[\left(-\lambda c_{n,\sigma}^{d1\dagger} c_{n,\sigma}^p - \lambda c_{n,\sigma}^{d2\dagger} c_{n,\sigma}^p - \lambda c_{n+1,\sigma}^{d1\dagger} c_{n,\sigma}^p - \lambda c_{n+1,\sigma}^{d2\dagger} c_{n,\sigma}^p \right. \right. \right. \\
 \left. \left. - c_{n,\sigma}^{d1\dagger} c_{n,\sigma}^{d2} - c_{n+1,\sigma}^{d1\dagger} c_{n,\sigma}^{d1} - c_{n+1,\sigma}^{d2\dagger} c_{n,\sigma}^{d2} - c_{n+1,\sigma}^{d1\dagger} c_{n,\sigma}^{d2} - c_{n+1,\sigma}^{d2\dagger} c_{n,\sigma}^{d1} + h.c. \right) \right. \\
 \left. + \epsilon^p c_{n,\sigma}^{p\dagger} c_{n,\sigma}^p + \epsilon_n^d c_{n,\sigma}^{d1\dagger} c_{n,\sigma}^{d1} + \epsilon_n^d c_{n,\sigma}^{d2\dagger} c_{n,\sigma}^{d2} \right] \\
 \left. + \epsilon_{N+1}^d c_{N+1,\sigma}^{d1\dagger} c_{N+1,\sigma}^{d1} + \epsilon_{N+1}^d c_{N+1,\sigma}^{d2\dagger} c_{N+1,\sigma}^{d2} \right\} \mathcal{P}, \tag{4.78}
 \end{aligned}$$

where the on-site potentials are $\epsilon^p = -\lambda^2$, $\epsilon_n^d = -4$ ($2 \leq n \leq N$), and $\epsilon_1^d = \epsilon_{N+1}^d = -2$. A unit cell is labeled by n . Here $c_{n,\sigma}^{d1}$ ($c_{n,\sigma}^{d2}$) is the annihilation operator on a d -site for $r = 3$ (4) in the n -th cell. The ground state is

$$\begin{aligned}
|\Phi_{G.S.}^C\rangle &= \mathcal{P} \prod_{i=1}^N \prod_{\sigma=\uparrow,\downarrow} \alpha_{n,\sigma}^{(C)\dagger} |0\rangle \\
&= \mathcal{P} \prod_{n=1}^N \prod_{\sigma=\uparrow,\downarrow} \left(c_{n,\sigma}^{d1\dagger} + c_{n,\sigma}^{d2\dagger} + c_{n+1,\sigma}^{d1\dagger} + c_{n+1,\sigma}^{d2\dagger} + \lambda c_{n,\sigma}^p \right) |0\rangle,
\end{aligned} \tag{4.79}$$

which is a $1/3$ -filling state.

2. Band structure in the single-electron problem

We investigate the single-electron problem for the Hamiltonian (4.78). We consider the system with an even number of the cells under the periodic boundary conditions. The similar calculation to that in Sec. IV A 2 leads the dispersion relations

$$\begin{aligned}
E_1 &= -\frac{1}{2} \left[6 + \lambda^2 + 4 \cos k + \sqrt{(6 + \lambda^2 + 4 \cos k)^2 - 8\lambda^2} \right] \\
E_2 &= -2 \\
E_3 &= -\frac{1}{2} \left[6 + \lambda^2 + 4 \cos k - \sqrt{(6 + \lambda^2 + 4 \cos k)^2 - 8\lambda^2} \right],
\end{aligned} \tag{4.80}$$

where 1, 2, and 3 are the band index, and k is the wave vector with (4.6). The energy gap between the lowest two bands is $\Delta = 0$ for $0 < \lambda < \sqrt{2}$ and $\Delta = \lambda^2$ for $\lambda > \sqrt{2}$.

The electron number in the ground state (4.79) corresponds to full-filling of the lowest band. Therefore, the ground state of the non-interacting system is metallic for $0 < \lambda < \sqrt{2}$ and is insulating for $\lambda > \sqrt{2}$.

3. Correlation functions

From (4.50), the norm of the ground state is

$$\langle \Phi_{G.S.}^C | \Phi_{G.S.}^C \rangle = \frac{e_1^N}{c_1} (R_{11}L_{11} + 4R_{21}L_{21} + R_{31}L_{31}), \tag{4.81}$$

where the corresponding matrices in (4.60) are

$$\begin{aligned}
\mathbf{T}_n &= \begin{pmatrix} 2 + 4\lambda^2 + \lambda^4 & 4\lambda^2 + 4\lambda^4 & \lambda^4 \\ 2 + \lambda^2 & 2 + 4\lambda^2 & \lambda^2 \\ 2 & 8 & 2 \end{pmatrix}, \quad \vec{I} = \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix}, \quad \vec{F} = \begin{pmatrix} 1 \\ 4 \\ 1 \end{pmatrix} \\
\mathbf{D} &= \begin{pmatrix} e_1 & 0 & 0 \\ 0 & e_2 & 0 \\ 0 & 0 & e_3 \end{pmatrix}, \quad \text{and} \quad \mathbf{C} = \begin{pmatrix} c_1 & 0 & 0 \\ 0 & c_2 & 0 \\ 0 & 0 & c_3 \end{pmatrix}.
\end{aligned} \tag{4.82}$$

The matrix $\mathbf{T}_n$ and the initial and the final vectors are derived in Appendix H 1. Here e_i ($i = 1, 2$, and 3) are the eigenvalues of $\mathbf{T}_n$

$$\begin{aligned}
e_1 &= \frac{1}{3} \left(s + \frac{t}{q} \right) \\
e_2 &= \frac{s}{3} + \frac{i}{12} \left[(1 + 2\sqrt{3}) \frac{t}{q} + (1 - 2\sqrt{3}) q \right] \\
e_3 &= \frac{s}{3} - \frac{i}{12} \left[(1 + 2\sqrt{3}) \frac{t}{q} + (1 - 2\sqrt{3}) q \right],
\end{aligned}$$

where $s = 6 + 8\lambda^2 + \lambda^4$, $t = \lambda^2(48 + 58\lambda^2 + 16\lambda^4 + \lambda^6)$, and $q = (p_1 + 3^{\frac{3}{2}}p_2i)^{\frac{1}{3}}$ with $p_1 = 468\lambda^4 + 512\lambda^6 + 183\lambda^8 + 24\lambda^{10} + \lambda^{12}$ and $p_2 = \lambda^6(4096 + 6736\lambda^2 + 4288\lambda^4 + 1328\lambda^6 + 192\lambda^8 + 9\lambda^{10})$. They satisfy $e_1 > e_2 > e_3 > 0$ for $\lambda \neq 0$. The matrix $\mathbf{L} = (L_{ij})$ ($\mathbf{R} = (R_{ij})$) is constructed from the left(right) eigenvectors. We choose them as we did in Sec. IV C, where $L_{j1} = (e_j - 2)^2 - 4e_j\lambda^2$, $L_{j2} = 4\lambda^2(e_j\lambda^2 + e_j - 2)$, $L_{j3} = \lambda^4(e_j + 2)$, $R_{1j} = (e_j - 2)^2 - 4e_j\lambda^2$, $R_{2j} = (2 + \lambda^2)e_j - 4$, and $R_{3j} = 2(e_j + 6)$.

We evaluate the expectation value of the number operator $\langle n_{i,\sigma}^\alpha \rangle$. The transfer matrices associated with $n_{i,\sigma}^\alpha$ are

$$\mathbf{N}_i^{(p)} = \begin{pmatrix} 2\lambda^2 + \lambda^4 & 2\lambda^2 + 4\lambda^4 & \lambda^4 \\ \frac{1}{2}\lambda^2 & 2\lambda^2 & \frac{1}{2}\lambda^2 \\ 0 & 0 & 0 \end{pmatrix}, \quad \mathbf{N}_i^{(d)} = \begin{pmatrix} 1 + \lambda^2 & 2\lambda^2 + \lambda^4 & \frac{1}{2}\lambda^4 \\ \frac{1}{2} & 1 + \lambda^2 & \frac{1}{2}\lambda^2 \\ 0 & 2 & 1 \end{pmatrix}. \quad (4.83)$$

They are derived in Appendix H 2. From (4.27), (4.81), (4.82), and (4.83), we obtain

$$\langle n_{i,\sigma}^\alpha \rangle = \begin{cases} \frac{\lambda^2}{4c_1} (4L_{11}R_{21} + L_{12}R_{31}) & \text{for } \alpha = p \\ \frac{1}{4c_1} [(2L_{11} - L_{12} + 2L_{13})R_{11} + (2L_{12} - 4L_{13})R_{21} + 2L_{13}R_{31}] & \text{for } \alpha = d. \end{cases} \quad (4.84)$$

It can be verified that there are two electrons per a unit cell as $\langle n_i^p \rangle + 2\langle n_i^d \rangle = 2$. The results are shown in Fig. 37. For $|\lambda| \ll 1$, on-site potentials satisfy the relations $\epsilon_d < \epsilon_p$ and $|\epsilon_p - \epsilon_d| \gg |\lambda|$ (the hybridization). There is almost one electron per d -site. The p -sites are almost empty. For $\lambda \gg 1$, on-site potentials satisfy the relations $\epsilon_p \ll \epsilon_d$ and $\epsilon_d - \epsilon_p \gg \lambda$. The p -sites are almost doubly occupied. The d -sites are almost empty.

From (3.31), (4.32), (4.82), (4.81), and (4.83), the density correlation functions are

$$\langle n_i^\alpha n_j^\alpha \rangle - \langle n_i^\alpha \rangle \langle n_j^\alpha \rangle = \begin{cases} \left(\frac{e_2}{e_1}\right)^{-|i-j|} \frac{\lambda^4}{4c_1c_2} R_2^{(p)} L_2^{(p)} + \left(\frac{e_3}{e_1}\right)^{-|i-j|} \frac{\lambda^4}{4c_1c_3} R_3^{(p)} L_3^{(p)} & \text{for } \alpha = p \\ \left(\frac{e_2}{e_1}\right)^{-|i-j|} \frac{1}{4c_1c_2} R_2^{(d)} L_2^{(d)} + \left(\frac{e_3}{e_1}\right)^{-|i-j|} \frac{1}{4c_1c_3} R_3^{(d)} L_3^{(d)} & \text{for } \alpha = d, \end{cases} \quad (4.85)$$

where

$$\begin{aligned} R_j^{(p)} &= 4L_{11}R_{1j} + L_{12}R_{3j} \\ L_j^{(p)} &= 4L_{j1}R_{21} + L_{j2}R_{31} \\ R_j^{(d)} &= (2L_{11} - L_{12} + 2L_{13})R_{1j} + 2(L_{12} - 2L_{13})R_{2j} + 2L_{13}R_{3j} \\ L_j^{(d)} &= L_{j1}(2R_{11}) + L_{j2}(-R_{11} + 2R_{21}) + 2L_{j3}(R_{11} - 2R_{21} + R_{31}). \end{aligned}$$

The density correlation functions take negative value and decay exponentially with distance. We show the results in Fig. 38. For $|\lambda| \ll 1$ and $\lambda \gg 1$, the density correlations are suppressed.

We evaluate the spin correlation function. The transfer matrices are

$$\begin{aligned} \mathbf{S}_n &= -2 \\ \mathbf{S}_i^{R,(p)} &= \left(\frac{1}{2}\lambda^2, \frac{5}{2}\lambda^2, 0 \right), \quad \mathbf{S}_j^{L,(p)} = \begin{pmatrix} 2\lambda^2 \\ 0 \\ 0 \end{pmatrix} \\ \mathbf{S}_i^{R,(d)} &= \left(\frac{1}{2}\lambda^2, 0, 0 \right), \quad \mathbf{S}_j^{L,(d)} = \begin{pmatrix} -\lambda^4 \\ -\lambda^2 \\ -2 \end{pmatrix}. \end{aligned} \quad (4.86)$$

They are derived in Appendix H 3. From (4.65), (4.81), and (4.86), we have

$$\langle S_i^z S_j^z \rangle = \left(-\frac{2}{e_1} \right)^{-|i-j|} \times \begin{cases} -\frac{\lambda^4}{2e_1c_1} (L_{11}R_{11} + 5L_{12}R_{21}) & \text{for } \beta = p \text{ and } \alpha = p \\ -\frac{\lambda^2}{2e_1c_1} L_{11}R_{11} & \text{for } \beta = p \text{ and } \alpha = d \\ -\frac{\lambda^2}{2e_1c_1} L_{13}R_{11} & \text{for } \beta = d \text{ and } \alpha = d. \end{cases} \quad (4.87)$$

The spin correlation functions decay exponentially with the oscillating sign. We show the results in Fig. 39. For $|\lambda| \ll 1$ and $\lambda \gg 1$, the spin correlations are suppressed.

We evaluate the singlet-pair correlation function. For (4.55)-(iv), the correlation functions are vanishing for $|k - i| \geq 2$. We evaluate them for (4.55)-(i) and (iii). (The position of the operators are shown in Figs. 49(e) and (f) in Appendix H 4.) The transfer matrices are

$$\mathbf{H}_n = 2, \quad \mathbf{H}_i^{R,(\gamma)} = \lambda^2 \begin{pmatrix} 1, & 5, & 0 \end{pmatrix}, \quad \mathbf{H}_j^{L,(\gamma)} = \begin{pmatrix} -4\lambda^2 \\ 0 \\ 0 \end{pmatrix}, \quad (4.88)$$

for $\gamma = p$ and dp . They are derived in Appendix H 4. From (4.68), (4.81), and (4.88), we obtain

$$\langle b_{i,j}^\dagger b_{k,l} \rangle = - \left(\frac{2}{e_1} \right)^{-|i-k|} \frac{2\lambda^4}{e_1 c_1} (L_{11}R_{11} + 5L_{12}R_{21}) \quad \text{for } \alpha, \beta = p, dp. \quad (4.89)$$

The singlet-pair correlation functions decay exponentially with distance. We show the results in Fig. 40. For $|\lambda| \ll 1$ and $\lambda \gg 1$, the correlations are suppressed.

We evaluate the correlation function $\langle c_{i,\sigma} c_{j,\sigma}^\dagger \rangle$. The transfer matrices are

$$\begin{aligned} \mathbf{G}_n &= -2 \begin{pmatrix} 1 + \lambda^2 & \lambda^2 \\ 1 & 1 \end{pmatrix} \\ \mathbf{G}_i^{R,(p)} &= -\lambda \begin{pmatrix} 2 & 2 & 0 \\ 1 & 4 & 1 \end{pmatrix}, \quad \mathbf{G}_j^{L,(p)} = -\lambda \begin{pmatrix} 2 & 0 \\ 1 & 1 \\ 0 & 0 \end{pmatrix} \\ \mathbf{G}_i^{R,(d)} &= - \begin{pmatrix} 1 + \lambda^2 & \lambda^2 & 0 \\ 1 & 1 & 0 \end{pmatrix}, \quad \mathbf{G}_j^{L,(d)} = - \begin{pmatrix} \lambda^2 + \lambda^4 & \lambda^4 \\ \frac{1}{2} + \lambda^2 & \lambda^2 \\ 2 & 2 \end{pmatrix}. \end{aligned} \quad (4.90)$$

They are derived in Appendix H 5. The matrix $\mathbf{G}_n$ is diagonalized as

$$\mathbf{G}_n = -2\tilde{\mathbf{R}}\tilde{\mathbf{D}}\tilde{\mathbf{C}}^{-1}\tilde{\mathbf{L}}, \quad (4.91)$$

where the matrices are shown in (4.71). The corresponding quantities are $g_1 = (2 + \lambda^2 + \lambda\omega_3)/2$ and $g_2 = (2 - \lambda^2 + \lambda\omega_3)/2$ with $\omega_3 = \sqrt{4 + \lambda^2}$. They satisfy $g_1 > g_2 > 0$ for $\lambda \neq 0$. We choose the matrices $\tilde{\mathbf{L}} = (\tilde{L}_{ij})$ and $\tilde{\mathbf{R}} = (\tilde{R}_{ij})$ as we did in Sec. IV C, where $\tilde{L}_{j1} = (g_j - 1)/\lambda^2$, $\tilde{L}_{j2} = 1$, $\tilde{R}_{1j} = g_j - 1$, and $\tilde{R}_{2j} = 1$. (See also (4.72).) From these matrices and (4.44), we obtain

$$\langle c_{i,\sigma} c_{j,\sigma}^\dagger \rangle = \left(-2\frac{g_1}{e_1} \right)^{-|i-j|} f_1^{(\alpha)} + \left(-2\frac{g_2}{e_1} \right)^{-|i-j|} f_2^{(\alpha)}, \quad (4.92)$$

where

$$\begin{aligned} f_m^{(p)} &= -\frac{1}{2c_1\tilde{c}_m e_1 g_m} [2(g_m - 1)L_{11} + g_m L_{12}] \\ &\quad \times \left[2(g_m - 1)(R_{11} + R_{21}) + \lambda^2(R_{11} + 4R_{21} + R_{31}) \right] \end{aligned} \quad (4.93)$$

$$f_m^{(d)} = \frac{2}{\lambda^2 c_1 \tilde{c}_m} [(g_m - 1)L_{12} + 4L_{13}] \left[(g_m - 1)R_{11} + \lambda^2 R_{21} \right]. \quad (4.94)$$

The correlation functions decay exponentially with the oscillating sign.

By the Fourier transformation of the correlation function $\langle c_{i,\sigma} c_{j,\sigma}^\dagger \rangle$, we obtain the momentum distribution functions for $\alpha = p$ and d

$$\langle n_{k,\sigma}^\alpha \rangle = f_1^{(\alpha)} F_1(k, r_1) + f_2^{(\alpha)} F_2(k, r_2) + f_0^{(\alpha)}, \quad (4.95)$$

where $F_i(k, r_i)$ is defined by (4.77), $r_i = -g_i/e_1$, and $f_0^{(\alpha)} = \langle n_{i,\sigma}^\alpha \rangle$. The results are shown in Fig. 41. There is no singularity in the momentum distribution functions. For the momentum distribution for p -site, it has a sharp peak at $k = \pi$ for $|\lambda| \ll 1$. The peak is, however, expected to vanish in the complete limit. It is almost flat for $\lambda \gg 1$. The momentum distribution for d -site is expected to be flat for the complete limit $|\lambda| \ll 1$.

4. Discussion

All the correlation functions under consideration decay exponentially with distance. These results suggest the existence of a finite excitation gap. Therefore, it is expected that the state is insulating. Their correlation lengths are $\xi_{nn} = \left[\ln \left(\frac{e_2}{e_1} \right) \right]^{-1}$, $\xi_{ss} = \xi_{bb} = \left[\ln \left(\frac{2}{e_1} \right) \right]^{-1}$, and $\xi_{cc} = \left[\ln \left(\frac{2g_1}{e_1} \right) \right]^{-1}$ (Fig. 42). (They satisfy the relation $\xi_{cc} > \xi_{nn} > \xi_{ss} = \xi_{bb}$.) We note that the spin correlation is antiferromagnetic.

We consider the region $|\lambda| \ll 1$. There is almost one electron per a d -site. The p -sites are almost empty. The correlation lengths are large. However, the correlation functions for the nearest neighbor sites vanish.

For $\lambda \gg 1$, There is almost two electrons per a p -site. The d -sites are almost empty. The correlation lengths and the correlation functions for the nearest neighbor sites vanish.

The ground state (4.79) is a 1/3-filling state. The filling factor corresponds to that of the band insulator in the non-interacting system for $\lambda > \sqrt{2}$. In the non-interacting system, we have the metal-insulator transition at $\lambda = \sqrt{2}$ by the variation of λ . However, the ground state (4.79) is insulating for any λ . The properties of these states are completely different.

V. ABSENCE OF THE PERSISTENT CURRENT

In Sec. IV, we have assumed the parameter λ_r to be real. Relaxing the condition, effects of a magnetic field is included by taking hopping matrix elements to be complex. Thus the effects of the magnetic field is investigated exactly for the systems of strongly correlated electrons described in this paper. Let us calculate the persistent current. Considering the system in a ring geometry and putting a flux through the ring, we can measure the Aharonov-Bohm effect and the persistent current [19,20,21,22,23]. In the ring geometry, we include the effect of the flux Φ by changing the hopping matrix elements of the N -th cell. We first classify sites in the N -th cell into two classes as: (i) sites which belong to the N -th unit cell and (ii) sites which are identified with sites in the cell C_1 . We denote the sets of the sites (i) and (ii) by $C_{N;u}$ and $C_{N;e}$, respectively. The cell Hamiltonian (2.2) associated with the N -th cell is obtained by choosing

$$\alpha_{N,\sigma}(\Phi) = \sum_{r=1}^{|C_N|} \tilde{\lambda}_r^{(N)}(\Phi) c_{r,\sigma}, \quad (5.1)$$

where

$$\tilde{\lambda}_r^{(N)}(\Phi) = \begin{cases} \lambda_r^{(N)} e^{i\Phi} & \text{for } r \in C_{N;e} \\ \lambda_r^{(N)} & \text{for } r \in C_{N;u}, \end{cases} \quad (5.2)$$

with real $\lambda_r^{(N)}$. From (5.1) and (2.3) for $1 \leq n \leq N-1$, the Hamiltonian is

$$H_S(\Phi) = -\mathcal{P} \sum_{\sigma=\uparrow,\downarrow} \sum_{x,y \in \Lambda_N} t_{x,y}(\Phi) c_{x,\sigma}^\dagger c_{y,\sigma} \mathcal{P}, \quad (5.3)$$

where

$$t_{x,y}(\Phi) = \sum_{n=1}^{N-1} t_{r,s}^{(n)} + t_{r,s}^{(N)}(\Phi), \quad \text{for } x = f(n, r) \text{ and } y = f(n, s), \quad (5.4)$$

with

$$t_{r,s}^{(n)} = \begin{cases} \lambda_r^{(n)} \lambda_s^{(m)} \delta_{n,m} & \text{for } r \neq s \\ 2 \left(\lambda_r^{(n)} \right)^2 & \text{for } r = s \text{ and } r \in C_{n;U=\infty} \\ \left(\lambda_r^{(n)} \right)^2 & \text{for } r = s \text{ and } r \in C_{n;U=0}, \end{cases} \quad (5.5)$$

$$(1 \leq m \leq N-1, \quad 1 \leq n \leq N-1)$$

$$t_{r,s}^{(N)}(\Phi) = \begin{cases} \left(\tilde{\lambda}_r^{(N)}(\Phi) \right)^* \lambda_s^{(N)} & \text{for } r \neq s \text{ and } r \in C_{N;e}, s \in C_{N;u} \\ \lambda_r^{(N)} \tilde{\lambda}_s^{(N)}(\Phi) & \text{for } r \neq s \text{ and } r \in C_{N;u}, s \in C_{N;e} \\ \lambda_r^{(N)} \lambda_s^{(N)} & \text{for } r \neq s \text{ and } r, s \in C_{N;u} \\ 2 \left(\lambda_r^{(N)} \right)^2 & \text{for } r = s \text{ and } r \in C_{N;U=\infty} \\ \left(\lambda_r^{(N)} \right)^2 & \text{for } r = s \text{ and } r \in C_{N;U=0}. \end{cases} \quad (5.6)$$

The ground state of $H_S(\Phi)$ is

$$|\Phi_{G.S.}(\Phi)\rangle = \mathcal{P} \prod_{\sigma=\uparrow,\downarrow} \left[\left(\prod_{n=1}^{N-1} \alpha_{n,\sigma}^\dagger \right) \alpha_{N,\sigma}^\dagger(\Phi) \right] |0\rangle. \quad (5.7)$$

The ground state energy is given explicitly by

$$\begin{aligned}
E_0(\Phi) &= - \sum_{n=1}^{N-1} \sum_{r \in C_n} 2 \left| \lambda_r^{(n)} \right|^2 - \sum_{r \in C_N} 2 \left| \tilde{\lambda}_r^{(N)}(\Phi) \right|^2 \\
&= - \sum_{n=1}^N \sum_{r \in C_n} 2 \left| \lambda_r^{(n)} \right|^2.
\end{aligned} \tag{5.8}$$

It is independent of the flux Φ . The persistent current I is evaluated by using the Byers-Yang relation [19]. We obtain

$$I \propto - \frac{\partial E_0(\Phi)}{\partial \Phi} = 0. \tag{5.9}$$

The persistent current is vanishing for any of the solvable models discussed here. This is consistent with our conclusion that the ground state is insulating.

Extending the discussion here, the absence of the persistent current can be shown in any dimensions for the models discussed in this paper.

VI. SUMMARY

We investigated three models with strongly correlated electrons which have the RVB state as an exact ground state. The number of the electrons per unit cell is restricted to be 2. The correlation functions are evaluated exactly using the transfer matrix method for the geometric representations of the valence-bond states [24]. The two-point correlation functions for spin, density, and singlet-Cooper-pairs are obtained for any distance. All the correlation functions decay exponentially with distance. The momentum distribution functions are also evaluated and there is no singularity. The results suggest that the ground states of the models are insulating. The persistent currents are also considered and turned out to be vanishing.

ACKNOWLEDGMENTS

We are grateful to H. Tasaki for valuable discussions. The method used in this work were developed by him. We would like to thank P.-A. Bares and P.-A. Lee for useful discussions and sending their article prior to publication. This work is, in part, supported by a grant for Priority Area from Ministry of Education, Science, and Culture Japan.

APPENDIX A

We describe the models by several authors [1,2,3,4] and those investigated in this paper using the cell construction of Tasaki (see Table I). The lattice is constructed by the cell in the second column in Table I. The cell for the line graph is constructed as follows. We define a lattice $\mathcal{L} = (\Lambda, B)$ where Λ is the set of the sites (vertices) and B is the set of the bonds (edges). The line graph $L(\mathcal{L}) = (\Lambda^L, B^L)$ constructed from a lattice Λ has the bonds of $\mathcal{L}$ as sites ($\Lambda^L = B$), and two sites are connected by a bond in B^L if the corresponding bonds in B have a site in common. The cell is defined by sites ($\in \Lambda^L$) which are connected by a bond ($\in B$) to a same site ($\in \Lambda$).

APPENDIX B

We first note the equalities

$$c_{i,\sigma} b_{i,j}^\dagger = \text{sgn}(\sigma) c_{j,\sigma}^\dagger (c_{i,\sigma} c_{i,\sigma}^\dagger), \quad (\text{B1})$$

and

$$b_{i,j} b_{i,k}^\dagger = \sum_{\sigma=\uparrow,\downarrow} (c_{i,\sigma} c_{i,\sigma}^\dagger) (c_{j,-\sigma} c_{k,-\sigma}^\dagger) + \Delta_i, \quad (\text{B2})$$

where $\Delta_i = -\sum_{\sigma=\uparrow,\downarrow} c_{i,\sigma}^\dagger (c_{k,-\sigma}^\dagger c_{j,\sigma}) c_{i,-\sigma}$ which has the property $\Delta_i |0\rangle = \langle 0| \Delta_i = 0$.

We show an equality. Consider a connected graph $W \cup W'$ with $2n$ ($n \geq 1$) bonds. We set $W = \{\{2, 3\}, \{4, 5\}, \dots, \{2n, 2n+1\}\}$ and $W' = \{\{1, 2\}, \{3, 4\}, \dots, \{2n-1, 2n\}\}$. We define the quantity

$$L(n; \sigma, \rho) = \left\langle 0 \left| \left(\prod_{k=1}^n b_{2k, 2k+1} \right) c_{1,\sigma} c_{2n+1,\rho}^\dagger \prod_{k=1}^n b_{2k-1, 2k}^\dagger \right| 0 \right\rangle. \quad (\text{B3})$$

For $n = 1$, from (B1) we have

$$\begin{aligned} L(1; \sigma, \rho) &= \left\langle 0 \left| b_{2,3} c_{1,\sigma} c_{3,\rho}^\dagger b_{1,2}^\dagger \right| 0 \right\rangle \\ &= - \left\langle 0 \left| b_{2,3} c_{3,\rho}^\dagger (c_{1,\sigma} b_{1,2}^\dagger) \right| 0 \right\rangle \\ &= -\text{sgn}(\sigma) \left\langle 0 \left| b_{2,3} c_{3,\rho}^\dagger c_{2,-\sigma} \right| 0 \right\rangle \\ &= \text{sgn}(\sigma) \text{sgn}(-\rho) \left\langle 0 \left| c_{2,-\sigma} c_{2,-\sigma}^\dagger c_{3,\rho} c_{3,\rho}^\dagger \right| 0 \right\rangle \\ &= -\delta_{\sigma,\rho} \end{aligned} \quad (\text{B4})$$

From (B1), we have

$$\begin{aligned} L(n; \sigma, \rho) &= \left\langle 0 \left| \left(\prod_{k=1}^n b_{2k, 2k+1} \right) c_{1,\sigma} c_{2n+1,\rho}^\dagger b_{1,2}^\dagger \prod_{k=2}^n b_{2k-1, 2k}^\dagger \right| 0 \right\rangle \\ &= -\text{sgn}(\sigma) \left\langle 0 \left| \left(\prod_{k=1}^n b_{2k, 2k+1} \right) c_{2n+1,\rho}^\dagger c_{2,-\sigma}^\dagger \prod_{k=2}^n b_{2k-1, 2k}^\dagger \right| 0 \right\rangle \\ &= -\text{sgn}(\sigma) \left\langle 0 \left| \left(\prod_{k=2}^n b_{2k, 2k+1} \right) b_{2,3} c_{2n+1,\rho}^\dagger c_{2,-\sigma}^\dagger \prod_{k=2}^n b_{2k-1, 2k}^\dagger \right| 0 \right\rangle \\ &= -\text{sgn}(\sigma) \text{sgn}(-\sigma) \left\langle 0 \left| \left(\prod_{k=2}^n b_{2k, 2k+1} \right) (-c_{3,\sigma}) c_{2n+1,\rho}^\dagger \prod_{k=2}^n b_{2k-1, 2k}^\dagger \right| 0 \right\rangle \\ &= - \left\langle 0 \left| \left(\prod_{k=2}^n b_{2k, 2k+1} \right) c_{3,\sigma} c_{2n+1,\rho}^\dagger \prod_{k=2}^n b_{2k-1, 2k}^\dagger \right| 0 \right\rangle. \end{aligned} \quad (\text{B5})$$

We change the labeling of the lattice sites by the rule $j \rightarrow j - 2$ and obtain

$$\begin{aligned}
L(n; \sigma, \rho) &= - \left\langle 0 \left| \left(\prod_{k=1}^{n-1} b_{2k, 2k+1} \right) c_{1, \sigma} c_{2n-1, \rho}^\dagger \prod_{k=1}^{n-1} b_{2k-1, 2k}^\dagger \right| 0 \right\rangle \\
&= -L(n-1; \sigma, \rho) \\
&= \dots \\
&= (-1)^{n-1} L(1; \sigma, \rho) \\
&= (-1)^n \delta_{\sigma, \rho}.
\end{aligned} \tag{B6}$$

We show (3.10). For the self-closed bonds and degenerate graph we have $w_j = 1$ and $w_j = 2$, respectively. Consider the non-degenerate loop $W_j \cup W'_j$ with $l_j = 2n$ ($n \geq 1$) bonds. We set $W_j = \{\{2, 3\}, \{4, 5\}, \dots, \{2n-2, 2n-1\}, \{2n, 2n+1 (= 1)\}\}$ and $W'_j = \{\{1, 2\}, \{3, 4\}, \dots, \{2n-1, 2n\}\}$. From (B2) and (B6) the weight is

$$\begin{aligned}
w_j &= \left\langle 0 \left| \prod_{k=1}^n b_{2k, 2k+1} \prod_{k=1}^n b_{2k-1, 2k}^\dagger \right| 0 \right\rangle \\
&= \left\langle 0 \left| \left(\prod_{k=1}^{n-1} b_{2k, 2k+1} \right) b_{2n, 2n+1} b_{2n-1, 2n}^\dagger \prod_{k=1}^{n-1} b_{2k-1, 2k}^\dagger \right| 0 \right\rangle \\
&= \left\langle 0 \left| \left(\prod_{k=1}^{n-1} b_{2k, 2k+1} \right) \left(\sum_{\sigma=\uparrow, \downarrow} c_{2n, \sigma} c_{2n, \sigma}^\dagger c_{1, -\sigma} c_{2n-1, -\sigma}^\dagger + \Delta_{2n} \right) \prod_{k=1}^{n-1} b_{2k-1, 2k}^\dagger \right| 0 \right\rangle \\
&= \sum_{\sigma=\uparrow, \downarrow} \left\langle 0 \left| \left(\prod_{k=1}^{n-1} b_{2k, 2k+1} \right) c_{2n, \sigma} c_{2n, \sigma}^\dagger c_{1, -\sigma} c_{2n-1, -\sigma}^\dagger \prod_{k=1}^{n-1} b_{2k-1, 2k}^\dagger \right| 0 \right\rangle \\
&= \sum_{\sigma=\uparrow, \downarrow} \left\langle 0 \left| \left(\prod_{k=1}^{n-1} b_{2k, 2k+1} \right) c_{1, -\sigma} c_{2(n-1)+1, -\sigma}^\dagger \prod_{k=1}^{n-1} b_{2k-1, 2k}^\dagger \right| 0 \right\rangle \\
&= \sum_{\sigma=\uparrow, \downarrow} L(n-1; -\sigma, -\sigma) \\
&= \sum_{\sigma=\uparrow, \downarrow} (-1)^{n-1} \delta_{-\sigma, -\sigma} \\
&= 2(-1)^{n-1} \\
&= 2(-1)^{l_j/2-1},
\end{aligned} \tag{B7}$$

where we used the relation $l = 2n$ in the last line.

APPENDIX C

We first note the equalities

$$\begin{aligned}
S_i^z b_{i,j}^\dagger &= \frac{1}{2} \tilde{b}_{i,j}^\dagger + \delta_{i,j} \\
S_i^z \tilde{b}_{i,j}^\dagger &= \frac{1}{2} b_{i,j}^\dagger - \tilde{\delta}_{ji},
\end{aligned} \tag{C1}$$

where

$$\tilde{b}_{i,j}^\dagger = c_{i,\uparrow}^\dagger c_{j,\downarrow}^\dagger + c_{i,\downarrow}^\dagger c_{j,\uparrow}^\dagger, \tag{C2}$$

is the creation operator of the triplet-pair between sites i and j and satisfies the relation $\tilde{b}_{i,j}^\dagger = -\tilde{b}_{ji}^\dagger$. Here

$$\begin{aligned}\delta_{i,j} &= -\frac{c_{i,\uparrow}^\dagger c_{j,\downarrow}^\dagger n_{i,\downarrow} - c_{i,\downarrow}^\dagger c_{j,\uparrow}^\dagger n_{i,\uparrow}}{2} \\ \tilde{\delta}_{i,j} &= -\frac{c_{i,\uparrow}^\dagger c_{j,\downarrow}^\dagger n_{i,\downarrow} + c_{i,\downarrow}^\dagger c_{j,\uparrow}^\dagger n_{i,\uparrow}}{2}\end{aligned}\tag{C3}$$

which have the properties $\delta_i|0\rangle = \langle 0|\delta_i = 0$ and $\tilde{\delta}_i|0\rangle = \langle 0|\tilde{\delta}_i = 0$.

We show (3.17). Consider the connected graph $W^{(x,y)} \cup W'^{(x,y)}$ with $2n$ ($n \geq 1$) bonds. We set $W^{(x,y)} = \{\{2,3\}, \{4,5\}, \dots, \{2n, 2n+1\}\}$ and $W'^{(x,y)} = \{\{1,2\}, \{3,4\}, \dots, \{2n-1, 2n\}\}$. We denote the right hand side of (3.17) by $S(m)$ as

$$S(m) = \left\langle 0 \left| \left(\prod_{k=1}^n b_{2k,2k+1} \right) S_1^z S_m^z \prod_{k=1}^n b_{2k-1,2k}^\dagger \right| 0 \right\rangle, \tag{C4}$$

where we set $x = 1$ and $y = m$. From (C1), we have

$$\begin{aligned}S(2m+1) &= \left\langle 0 \left| \left(\prod_{k=1}^n b_{2k,2k+1} \right) S_1^z S_{2m+1}^z \prod_{k=1}^n b_{2k-1,2k}^\dagger \right| 0 \right\rangle \\ &= \left\langle 0 \left| \left(\prod_{k=1}^{m-1} b_{2k,2k+1} \right) \left(\prod_{k=m+1}^n b_{2k,2k+1} \right) b_{2m,2m+1} S_{2m+1}^z S_1^z \prod_{k=1}^n b_{2k-1,2k}^\dagger \right| 0 \right\rangle \\ &= \left\langle 0 \left| \left(\prod_{k=1}^{m-1} b_{2k,2k+1} \right) \left(\prod_{k=m+1}^n b_{2k,2k+1} \right) \left(\frac{1}{2} \tilde{b}_{2m+1,2m} + \delta_{2m+1,2m} \right) S_1^z \prod_{k=1}^n b_{2k-1,2k}^\dagger \right| 0 \right\rangle \\ &= \left\langle 0 \left| \left(\prod_{k=1}^{m-1} b_{2k,2k+1} \right) \left(\prod_{k=m+1}^n b_{2k,2k+1} \right) \left(-\frac{1}{2} \tilde{b}_{2m,2m+1} \right) S_1^z \prod_{k=1}^n b_{2k-1,2k}^\dagger \right| 0 \right\rangle \\ &= -\left\langle 0 \left| \left(\prod_{k=1}^{m-1} b_{2k,2k+1} \right) \left(\prod_{k=m+1}^n b_{2k,2k+1} \right) b_{2m-1,2m} S_{2m}^z S_1^z \prod_{k=1}^n b_{2k-1,2k}^\dagger \right| 0 \right\rangle \\ &= -\left\langle 0 \left| \left(\prod_{k=1}^n b_{2k,2k+1} \right) S_1^z S_{2m}^z \prod_{k=1}^n b_{2k-1,2k}^\dagger \right| 0 \right\rangle \\ &= -\left\langle 0 \left| \left(\prod_{k=1}^n b_{2k,2k+1} \right) S_1^z S_{2m}^z b_{2m-1,2m}^\dagger \left(\prod_{k=1}^{m-1} b_{2k-1,2k}^\dagger \right) \prod_{k=m+1}^n b_{2k-1,2k}^\dagger \right| 0 \right\rangle \\ &= -\left\langle 0 \left| \left(\prod_{k=1}^n b_{2k,2k+1} \right) S_1^z \left(\frac{1}{2} \tilde{b}_{2m,2m-1}^\dagger + \delta_{2m,2m-1} \right) \left(\prod_{k=1}^{m-1} b_{2k-1,2k}^\dagger \right) \prod_{k=m+1}^n b_{2k-1,2k}^\dagger \right| 0 \right\rangle \\ &= -\left\langle 0 \left| \left(\prod_{k=1}^n b_{2k,2k+1} \right) S_1^z \left(-\frac{1}{2} \tilde{b}_{2m-1,2m}^\dagger \right) \left(\prod_{k=1}^{m-1} b_{2k-1,2k}^\dagger \right) \prod_{k=m+1}^n b_{2k-1,2k}^\dagger \right| 0 \right\rangle \\ &= (-1)^2 \left\langle 0 \left| \left(\prod_{k=1}^n b_{2k,2k+1} \right) S_1^z S_{2m-1}^z b_{2m-1,2m}^\dagger \left(\prod_{k=1}^{m-1} b_{2k-1,2k}^\dagger \right) \prod_{k=m+1}^n b_{2k-1,2k}^\dagger \right| 0 \right\rangle \\ &= (-1)^2 \left\langle 0 \left| \left(\prod_{k=1}^n b_{2k,2k+1} \right) S_1^z S_{2m-1}^z \prod_{k=1}^n b_{2k-1,2k}^\dagger \right| 0 \right\rangle \\ &= (-1)^2 S(2m-1) \\ &= \dots \\ &= (-1)^{2m} S(1) \\ &= (-1)^{2m} \left\langle 0 \left| \left(\prod_{k=1}^n b_{2k,2k+1} \right) S_1^z S_1^z \prod_{k=1}^n b_{2k-1,2k}^\dagger \right| 0 \right\rangle \\ &= \frac{(-1)^{2m}}{4} \left\langle 0 \left| \prod_{k=1}^n b_{2k,2k+1} \prod_{k=1}^n b_{2k-1,2k}^\dagger \right| 0 \right\rangle.\end{aligned}\tag{C5}$$

Similarly, we have

$$S(2m) = (-1)^{2m-1} \frac{1}{4} \left\langle 0 \left| \prod_{k=1}^n b_{2k,2k+1} \prod_{k=1}^n b_{2k-1,2k}^\dagger \right| 0 \right\rangle, \quad (\text{C6})$$

Therefore, we obtain

$$S(m) = \frac{1}{4} (-1)^{d(x,y)} w_j \quad (\text{C7})$$

where we used the relation $d(x, y) = m - 1$ and the definition of w_j .

APPENDIX D

We show (3.22). Consider the line $W^{(x',y')} \cup W'^{(x',y')}$ with $2n$ ($n \geq 1$) bonds. We set $W^{(x',y')} = \{\{2, 3\}, \{4, 5\}, \dots, \{2n, 2n+1 (= y')\}\}$ and $W'^{(x',y')} = \{\{1 (= x'), 2\}, \{3, 4\}, \dots, \{2n-1, 2n\}\}$. From (B3), the weight is

$$\begin{aligned} \left\langle 0 \left| \left(\prod_{k=1}^n b_{2k,2k+1} \right) c_{1,\sigma} c_{2n+1,\rho}^\dagger \prod_{k=1}^n b_{2k-1,2k}^\dagger \right| 0 \right\rangle &= L(n; \sigma, \sigma) \\ &= (-1)^n \\ &= (-1)^{l(x',y')/2} \end{aligned} \quad (\text{D1})$$

where we used the relation $l(x', y') = 2n$.

APPENDIX E

We show (3.28). Consider the graph $W^{(x)} \cup W'^{(x)}$, we set $W^{(x)} = \{\{1 (= x), 2\}, \{3, 4\}, \dots, \{2n-1, 2n\}\}$ and $W'^{(x)} = \{\{2, 3\}, \{4, 5\}, \dots, \{2n, 1\}\}$. We have

$$\begin{aligned} &\left\langle 0 \left| \left(\prod_{k=1}^n b_{2k-1,2k} \right) n_{1,\sigma} \prod_{k=1}^n b_{2k,2k+1}^\dagger \right| 0 \right\rangle \\ &= \left\langle 0 \left| \left(\prod_{k=2}^n b_{2k-1,2k} \right) b_{1,2} (1 - c_{1,\sigma} c_{1,\sigma}^\dagger) b_{2n,1}^\dagger \prod_{k=1}^{n-1} b_{2k,2k+1}^\dagger \right| 0 \right\rangle \\ &= \left\langle 0 \left| \prod_{k=1}^n b_{2k-1,2k} \prod_{k=1}^n b_{2k,2k+1}^\dagger \right| 0 \right\rangle - \left\langle 0 \left| \left(\prod_{k=1}^n b_{2k-1,2k} \right) c_{1,\sigma} c_{1,\sigma}^\dagger \prod_{k=1}^n b_{2k,2k+1}^\dagger \right| 0 \right\rangle. \end{aligned} \quad (\text{E1})$$

From (B3), the second term is

$$\begin{aligned} &\left\langle 0 \left| \left(\prod_{k=1}^n b_{2k-1,2k} \right) c_{1,\sigma} c_{1,\sigma}^\dagger \prod_{k=1}^n b_{2k,2k+1}^\dagger \right| 0 \right\rangle \\ &= \left\langle 0 \left| \left(\prod_{k=2}^n b_{2k-1,2k} \right) b_{1,2} c_{1,\sigma} c_{1,\sigma}^\dagger b_{2n,1}^\dagger \prod_{k=1}^{n-1} b_{2k,2k+1}^\dagger \right| 0 \right\rangle \\ &= \left\langle 0 \left| \left(\prod_{k=2}^n b_{2k-1,2k} \right) (-b_{1,1} c_{2,\sigma}) (-c_{2n,\sigma}^\dagger b_{1,1}^\dagger) \prod_{k=1}^{n-1} b_{2k,2k+1}^\dagger \right| 0 \right\rangle \\ &= \left\langle 0 \left| \left(\prod_{k=2}^n b_{2k-1,2k} \right) c_{2,\sigma} c_{2n,\sigma}^\dagger \prod_{k=1}^{n-1} b_{2k,2k+1}^\dagger \right| 0 \right\rangle \\ &= \left\langle 0 \left| \left(\prod_{k=1}^{n-1} b_{2k,2k+1} \right) c_{1,\sigma} c_{2n-1,\sigma}^\dagger \prod_{k=1}^{n-1} b_{2k-1,2k}^\dagger \right| 0 \right\rangle \end{aligned}$$

$$\begin{aligned}
&= L(n-1; \sigma, \sigma) \\
&= (-1)^{n-1} \\
&= (-1)^{l(x)/2-1}.
\end{aligned} \tag{E2}$$

The fourth line is obtained by renaming the site j to $j-1$. We used the relation $l(x) = 2(n-1)$. From (B7) and (E2), we have

$$\begin{aligned}
\left\langle 0 \left| \prod_{k=1}^n b_{2k-1, 2k} n_{1, \sigma} \prod_{k=1}^n b_{2k, 2k+1}^\dagger \right| 0 \right\rangle &= 2(-1)^{l(x)/2-1} - (-1)^{l(x)/2-1} \\
&= (-1)^{l(x)/2-1}.
\end{aligned} \tag{E3}$$

APPENDIX F

We show (3.35). For (i), the sets $W^{(x,y)}$ and $W'^{(x,y)}$ are empty. The right hand side of (3.34) is

$$w_j(x, y; \sigma) = \frac{1}{2} \left\{ \langle 0 | c_{x, \sigma} c_{y, \sigma} c_{y, \sigma}^\dagger c_{x, \sigma}^\dagger | 0 \rangle + \langle 0 | c_{x, \sigma} c_{y, -\sigma} c_{y, -\sigma}^\dagger c_{x, \sigma}^\dagger | 0 \rangle \right\} = 1, \tag{F1}$$

where we used the equality $\langle 0 | c_{x, \sigma} c_{y, \sigma} c_{y, \sigma}^\dagger c_{x, \sigma}^\dagger | 0 \rangle = \langle 0 | c_{x, \sigma} c_{y, -\sigma} c_{y, -\sigma}^\dagger c_{x, \sigma}^\dagger | 0 \rangle = 1$.

For (ii), we suppose that the site x belongs to the graph. From (3.28), the right hand side of (3.34) is

$$\begin{aligned}
w_j(x, y; \sigma) &= \frac{1}{2} \left\{ \left\langle 0 \left| c_{y, \sigma} c_{y, \sigma}^\dagger \right| 0 \right\rangle \left\langle 0 \left| \left(\prod_{\{u', v'\} \in W'(x)} b_{u', v'} \right) c_{x, \sigma} c_{x, \sigma}^\dagger \prod_{\{u, v\} \in W(x)} b_{u, v}^\dagger \right| 0 \right\rangle \right. \\
&\quad \left. + \left\langle 0 \left| c_{y, -\sigma} c_{y, -\sigma}^\dagger \right| 0 \right\rangle \left\langle 0 \left| \left(\prod_{\{u', v'\} \in W'(x)} \right) b_{u', v'} c_{x, \sigma} c_{x, \sigma}^\dagger \prod_{\{u, v\} \in W(x)} b_{u, v}^\dagger \right| 0 \right\rangle \right\} \\
&= (-1)^{l(x)/2-1},
\end{aligned} \tag{F2}$$

where we used the equality $\langle 0 | c_{y, \sigma} c_{y, \sigma}^\dagger | 0 \rangle = \langle 0 | c_{y, -\sigma} c_{y, -\sigma}^\dagger | 0 \rangle = 1$.

For (iii), the right hand side of (3.34) is

$$\begin{aligned}
w_j(x, y; \sigma) &= \frac{1}{2} \left\{ \left\langle 0 \left| \left(\prod_{\{u', v'\} \in W'(x,y)} b_{u', v'} \right) c_{y, \sigma} c_{y, \sigma}^\dagger \prod_{\{u, v\} \in W(x,y)} b_{u, v}^\dagger \right| 0 \right\rangle \right. \\
&\quad \left\langle 0 \left| \left(\prod_{\{u', v'\} \in W'(x,y)} b_{u', v'} \right) c_{x, \sigma} c_{x, \sigma}^\dagger \prod_{\{u, v\} \in W(x,y)} b_{u, v}^\dagger \right| 0 \right\rangle \\
&\quad + \left\langle 0 \left| \left(\prod_{\{u', v'\} \in W'(x,y)} b_{u', v'} \right) c_{y, -\sigma} c_{y, -\sigma}^\dagger \prod_{\{u, v\} \in W(x,y)} b_{u, v}^\dagger \right| 0 \right\rangle \\
&\quad \left. \left\langle 0 \left| \left(\prod_{\{u', v'\} \in W'(x,y)} b_{u', v'} \right) c_{x, \sigma} c_{x, \sigma}^\dagger \prod_{\{u, v\} \in W(x,y)} b_{u, v}^\dagger \right| 0 \right\rangle \right\} \\
&= (-1)^{l(x)/2-1} (-1)^{l(y)/2-1},
\end{aligned} \tag{F3}$$

where we used (3.28).

For (iv), consider the graph $W^{(x,y)} \cup W'^{(x,y)}$. We set $W^{(x,y)} = \{\{1(=x), 2\}, \{3, 4\}, \dots, \{2n-1, 2n\}\}$ and $W'^{(x,y)} = \{\{2, 3\}, \{4, 5\}, \dots, \{2n, 1\}\}$. We denote one of the terms in the right hand side of (3.34) by $G(n, j; \sigma, \tau)$ as

$$G(n, j; \sigma, \tau) = \left\langle 0 \left| \left(\prod_{k=1}^n b_{2k-1, 2k} \right) c_{1, \sigma} c_{j, \tau} c_{j, \tau}^\dagger c_{1, \sigma}^\dagger \prod_{k=1}^n b_{2k, 2k+1}^\dagger \right| 0 \right\rangle. \quad (\text{F4})$$

From (B1), we have

$$\begin{aligned} G(n, j; \sigma, \tau) &= \left\langle 0 \left| \left(\prod_{k=2}^n b_{2k-1, 2k} \right) b_{1, 2} c_{1, \sigma} c_{j, \tau} c_{j, \tau}^\dagger c_{1, \sigma}^\dagger b_{2n, 1}^\dagger \prod_{k=1}^{n-1} b_{2k, 2k+1}^\dagger \right| 0 \right\rangle \\ &= \left\langle 0 \left| \left(\prod_{k=2}^n b_{2k-1, 2k} \right) (-b_{1, 1} c_{2, \sigma}) c_{j, \tau} c_{j, \tau}^\dagger (-c_{2n, \sigma}^\dagger b_{1, 1}^\dagger) \prod_{k=1}^{n-1} b_{2k, 2k+1}^\dagger \right| 0 \right\rangle \\ &= \left\langle 0 \left| \left(\prod_{k=2}^n b_{2k-1, 2k} \right) c_{2, \sigma} c_{j, \tau} c_{j, \tau}^\dagger c_{2n, \sigma}^\dagger \prod_{k=1}^{n-1} b_{2k, 2k+1}^\dagger \right| 0 \right\rangle \\ &= \left\langle 0 \left| \left(\prod_{k=1}^{n-1} b_{2k, 2k+1} \right) c_{1, \sigma} c_{j-1, \tau} c_{j-1, \tau}^\dagger c_{2n-1, \sigma}^\dagger \prod_{k=1}^{n-1} b_{2k-1, 2k}^\dagger \right| 0 \right\rangle. \end{aligned} \quad (\text{F5})$$

The last line is obtained by renaming of the lattice sites by the rule $k \rightarrow k - 1$. For $j = 2m$, we have

$$\begin{aligned} G(n-1, 2m; \sigma, \tau) &= \left\langle 0 \left| \left(\prod_{k=1}^{n-1} b_{2k, 2k+1} \right) c_{1, \sigma} c_{2m-1, \tau} c_{2m-1, \tau}^\dagger c_{2(n-1)+1, \sigma}^\dagger \prod_{k=1}^{n-1} b_{2k-1, 2k}^\dagger \right| 0 \right\rangle \\ &= \left\langle 0 \left| \left(\prod_{k=1}^{n-1} b_{2k, 2k+1} \right) c_{2m-1, \tau} c_{2m-1, \tau}^\dagger c_{2(n-1)+1, \sigma}^\dagger (-c_{1, \sigma} b_{1, 2}^\dagger) \prod_{k=2}^{n-1} b_{2k-1, 2k}^\dagger \right| 0 \right\rangle \\ &= -\text{sgn}(\sigma) \left\langle 0 \left| \left(\prod_{k=1}^{n-1} b_{2k, 2k+1} \right) c_{2m-1, \tau} c_{2m-1, \tau}^\dagger c_{2(n-1)+1, \sigma}^\dagger c_{2, -\sigma} \prod_{k=2}^{n-1} b_{2k-1, 2k}^\dagger \right| 0 \right\rangle \\ &= -\text{sgn}(\sigma) \left\langle 0 \left| \left(\prod_{k=2}^{n-1} b_{2k, 2k+1} \right) (b_{2, 3} c_{2, -\sigma}) c_{2m-1, \tau} c_{2m-1, \tau}^\dagger c_{2(n-1)+1, \sigma}^\dagger \prod_{k=2}^{n-1} b_{2k-1, 2k}^\dagger \right| 0 \right\rangle \\ &= - \left\langle 0 \left| \left(\prod_{k=2}^{n-1} b_{2k, 2k+1} \right) c_{3, \sigma} c_{2m-1, \tau} c_{2m-1, \tau}^\dagger c_{2(n-1)+1, \sigma}^\dagger \prod_{k=2}^{n-1} b_{2k-1, 2k}^\dagger \right| 0 \right\rangle. \end{aligned} \quad (\text{F6})$$

We change the labeling of the lattice sites by the rule $j \rightarrow j - 2$ and obtain

$$\begin{aligned} G(n-1, 2m; \sigma, \tau) &= - \left\langle 0 \left| \left(\prod_{k=1}^{n-2} b_{2k, 2k+1} \right) c_{1, \sigma} c_{2(m-1)-1, \tau} c_{2(m-1)-1, \tau}^\dagger c_{2(n-2)+1, \sigma}^\dagger \prod_{k=1}^{n-2} b_{2k-1, 2k}^\dagger \right| 0 \right\rangle \\ &= -G(n-1, 2(m-1); \sigma, \tau) \\ &= \dots \\ &= (-1)^m G(n-m-1, 2; \sigma, \tau) \\ &= (-1)^m \left\langle 0 \left| \left(\prod_{k=1}^{n-m-1} b_{2k, 2k+1} \right) c_{1, \sigma} c_{1, \tau} c_{1, \tau}^\dagger c_{2(n-m-1)+1, \sigma}^\dagger \prod_{k=1}^{n-m-1} b_{2k-1, 2k}^\dagger \right| 0 \right\rangle \\ &= (-1)^m \left\langle 0 \left| \left(\prod_{k=1}^{n-m-1} b_{2k, 2k+1} \right) c_{1, \sigma} c_{1, \tau} c_{2(n-m-1)+1, \sigma}^\dagger (-c_{1, \tau}^\dagger b_{1, 2}^\dagger) \prod_{k=2}^{n-m-1} b_{2k-1, 2k}^\dagger \right| 0 \right\rangle \\ &= (-1)^m \left\langle 0 \left| \left(\prod_{k=1}^{n-m-1} b_{2k, 2k+1} \right) c_{1, \sigma} c_{1, \tau} b_{1, 1}^\dagger c_{2(n-m-1)+1, \sigma}^\dagger c_{2, \tau}^\dagger \prod_{k=2}^{n-m-1} b_{2k-1, 2k}^\dagger \right| 0 \right\rangle \\ &= (-1)^m \text{sgn}(\tau) \delta_{\sigma, -\tau} \left\langle 0 \left| \left(\prod_{k=1}^{n-m-1} b_{2k, 2k+1} \right) c_{2(n-m-1)+1, \sigma}^\dagger c_{2, \tau}^\dagger \prod_{k=2}^{n-m-1} b_{2k-1, 2k}^\dagger \right| 0 \right\rangle \\ &= (-1)^m \delta_{\sigma, -\tau} \left\langle 0 \left| \left(\prod_{k=2}^{n-m-1} b_{2k, 2k+1} \right) c_{3, -\tau}^\dagger c_{2(n-m-1)+1, \sigma}^\dagger \prod_{k=2}^{n-m-1} b_{2k-1, 2k}^\dagger \right| 0 \right\rangle. \end{aligned} \quad (\text{F7})$$

We change the labeling of the lattice sites by the rule $k \rightarrow k - 2$ and obtain

$$\begin{aligned}
G(n-1, 2m; \sigma, \tau) &= (-1)^m \delta_{\sigma, -\tau} \left\langle 0 \left| \left(\prod_{k=1}^{n-m-2} b_{2k, 2k+1} \right) c_{1, -\tau}^\dagger c_{2(n-m-2)+1, \sigma}^\dagger \prod_{k=1}^{n-m-2} b_{2k-1, 2k}^\dagger \right| 0 \right\rangle \\
&= (-1)^m \delta_{\sigma, -\tau} L(n-m-2; \sigma, -\tau) \\
&= (-1)^m \delta_{\sigma, -\tau} \times (-1)^{n-m-2} \delta_{\sigma, -\tau} \\
&= (-1)^{n-1} \delta_{\sigma, -\tau},
\end{aligned} \tag{F8}$$

where we used (B6). For $j = 2m - 1$, the similar calculation leads

$$G(2m-1; \sigma, \tau) = (-1)^{n-1} \delta_{\sigma, \tau}. \tag{F9}$$

Combining (F8) and (F9), (F5) is

$$\left\langle 0 \left| \left(\prod_{k=1}^n b_{2k, 2k+1} \right) c_{1, \sigma} c_{y, \tau} c_{y, \tau}^\dagger c_{1, \sigma}^\dagger \prod_{k=1}^n b_{2k-1, 2k}^\dagger \right| 0 \right\rangle = (-1)^{n-1} \delta_{\sigma, (-1)^{d(x, y)} \tau}. \tag{F10}$$

We obtain the weight

$$\begin{aligned}
w_j(x, y; \sigma) &= \frac{1}{2} [G(n, y; \sigma, \sigma) + G(n, y; \sigma, -\sigma)] \\
&= (-1)^{l(x, y)/2-1} \times \frac{\delta_{\sigma, (-1)^{d(x, y)} \sigma} + \delta_{\sigma, (-1)^{d(x, y)+1} \sigma}}{2} \\
&= \frac{(-1)^{l(x, y)/2-1}}{2},
\end{aligned} \tag{F11}$$

where we used the relation $n = l(x, y)/2$.

APPENDIX G: DERIVATION OF TRANSFER MATRICES FOR MODEL B

In Model B, the sites which is identified in the cell construction are p -sites and there exists the sites with four bonds in the geometric representation. We need the procedures shown in Fig. 5 (b) and (c) to calculate the contribution from the graph. Since we do not need the procedure shown in Fig. 5 (a) except for the correlation function $\langle c_{i,\sigma} c_{j,\sigma}^\dagger \rangle$, $m_j = 0$ in (3.11), (3.19), (3.30), (3.37), and (3.24).

1. Norm of the ground state

For the sake of convenience, we draw the lattice shown in Fig. 25(b) as Fig. 43(a). The ground state is written by (3.3) geometrically, where an example of the valence-bond configuration V is shown in Fig. 43(b). The geometric representation of the norm is (3.11), where an example of the graph $V \cup V'$ is shown in Fig. 43(c). We first evaluate the contribution from a graph $V \cup V'$. It can be decomposed into the subgraphs $U_i \cup U'_i$ ($i = 1, 2, \dots, n(V \cup V')$). The Loops which are extending over more than two cells are allowed. (See Figs. 43(c) and (j)). After the elimination of sites with four non-closed bonds (by the procedure shown in Fig. 5(b) or (c)) we have one degenerate loop and self-closed bonds (Fig. 43(d)). Therefore, the loop (Fig. 43 (j)) has weight 2.

We derive the matrix $\mathbf{T}_n$ in (4.82). A subgraph $U_i \cup U'_i$ is constructed by the five kinds of cells shown in (Fig. 44). The sum over the graph $V \cup V'$ is equivalent to that over all the combination of above five cells under the restriction that a p -site has at most four valence-bonds. (The restriction means, for example, that the identification of the right p -site in Fig. 44(b) with the left p -site in Fig. 44(c) is forbidden.) We shall always take into account the restriction hereafter and it should be understood implicitly. We have to distinguish three cases due to the restriction. Let A_n , B_n , and C_n be the quantity defined by the right-hand side of (3.6) on the lattice Λ_n . For A_n , the sum is taken over all the combination of the cells shown in Fig. 44 with the restriction that the n -th cell is represented by Fig. 44(a) or (b). For B_n and C_n , the sum is taken as was done for A_n with the restriction that the n -th cell is represented either by Fig. 44(c) or (d) for B_n and by (e) for C_n . They are represented diagrammatically

$$A_n = \tag{G1}$$

$$B_n = \tag{G2}$$

$$C_n = \tag{G3}$$

The recursion relations are

$$\begin{aligned} A_n &= \\ &= \lambda_2^4 A_{n-1} + 2\lambda_2^2 A_{n-1} + 2\lambda_2^2 B_{n-1} \end{aligned} \tag{G4}$$

$$\begin{aligned} B_n &= \\ &= \lambda_1^2 A_{n-1} + 2\lambda_1^2 B_{n-1} + \lambda_1^2 C_{n-1} + \lambda_1^2 \lambda_2^2 A_{n-1} + \lambda_1^2 \lambda_2^2 B_{n-1} \end{aligned} \tag{G5}$$

$$\begin{aligned} C_n &= \\ &= \lambda_1^4 A_{n-1} + 2\lambda_1^4 B_{n-1} + \lambda_1^4 C_{n-1}, \end{aligned} \tag{G6}$$

where we adopt the following rule to assign weight 2 to the loop which is extending over more than two cells. We assign the coefficient 1 for all the terms in B_n , since the loop may continue to the $n+1$ -th cell. In the third term in A_n and the second term in B_n and C_n we assign weight 2, since we make sure that the loop finishes there. The corresponding matrix is $\mathbf{T}_n$ in (4.60). Since any cell in Fig. 44 is allowed at the boundaries, the initial and the final vectors are $\vec{I} \equiv (A_0, B_0, C_0)^T = (1, 0, 0)^T$ and $\vec{F} \equiv (A_N, B_N, C_N)^T = (1, 2, 1)^T$, respectively.

2. Expectation value of the number operator

The geometric representation of the expectation value is (3.29), where an example of the graph $V \cup V'$ is shown in Fig. 43(e). We derive the matrix $\mathbf{N}_i^{(p)}$. We have five kinds of graphs on the i -th cell (Fig. 45(a)-(e)). Let $A_i^{(p)}$, $B_i^{(p)}$, and $C_i^{(p)}$ be the quantity defined by the right-hand side of (3.29) on the lattice Λ_i . The restriction for the sum is that the i -th cell is represented either by Fig. 45(a) or (b) for $A_i^{(p)}$, by (c) or (d) for $B_i^{(p)}$, and by (e) for $C_i^{(p)}$. The recursion relations are

$$\begin{aligned} A_i^{(p)} &= \\ &= \lambda_2^2 A_{i-1} + 2\lambda_2^2 B_{i-1} + \lambda_2^4 A_{i-1} \end{aligned} \quad (\text{G7})$$

$$\begin{aligned} B_i^{(p)} &= \\ &= \frac{1}{2} \lambda_1^2 \lambda_2^2 A_{i-1} + \lambda_1^2 \lambda_2^2 B_{i-1} + \lambda_1^2 B_{i-1} + \lambda_1^2 C_{i-1} \end{aligned} \quad (\text{G8})$$

$$\begin{aligned} C_i^{(p)} &= \\ &= \lambda_1^4 B_{i-1}, \end{aligned} \quad (\text{G9})$$

where we used the same rule in subsection G1 for the subgraph without the number operator. For the subgraph with the operator, we adopt the following rule to assign the weight (3.28). For the first and the third terms in $A_i^{(p)}$, the third and fourth terms in $B_i^{(p)}$, and $C_i^{(p)}$, we assigned coefficient 1. For the second term in $A_i^{(p)}$, we assigned weight 2, since the loop is decomposed into self-closed bonds and a degenerate loop which finishes there. For the second term in $B_i^{(p)}$, we assigned coefficient 1, since the loop is decomposed into self-closed bonds and a degenerate loop which may continue to the $i+1$ -th cell. For the first term in $B_i^{(p)}$, we assigned coefficient $1/2$ to cancel weight 2 which is assigned at another end of the loop where we regard it as the end of a loop without the number operator. The corresponding matrix is $\mathbf{N}_i^{(p)}$ in (4.61). Using the cells shown in Fig. 45(f) and (g), the similar calculation leads $\mathbf{N}_i^{(d)}$ in (4.61).

3. Spin correlation function

The geometric representation of the expectation value is (3.18), where an example of the graph $V \cup V'$ is shown in Fig. 43(f). From the procedure in Fig. 5(b) or (c), the graph with the spin operators is decomposed into a degenerate loop with the sites i and j and the self-closed bonds. Therefore, $d(i, j) = 1$ in (3.18). The degenerate loop has weight $-1 \times \frac{1}{4} \times 2$. We assign $\frac{1}{2}$ at the i -th cell and $-\frac{1}{2} \times 2$ at the j -th cell in the recursion relation. We derive the matrix $\mathbf{S}_n$ in (4.54). Let S_n be the quantity defined by a sum. The sum is taken over $V \cup V'$ on the lattice Λ_n such that the graph consists of loops shown in Fig. 44 on the k -th cell ($1 \leq k \leq i-1$) and that shown in Fig. 44(c) on the l -th cell ($i \leq l \leq n$). The recursion relation is

$$\begin{aligned} S_n &= \\ &= \\ &= \lambda_1^2 \lambda_2^2 S_{n-1}, \end{aligned} \quad (\text{G10})$$

and the corresponding matrix is $\mathbf{S}_n$ in (4.64).

We derive the matrix $\mathbf{S}_i^{R,(p)}$. The graph on the i -th cell is shown in Fig. 46(a). Let $S_i^{(p)}$ be the quantity defined by a sum. The sum is taken over $V \cup V'$ on the lattice Λ_i such that the graph consists of loops shown in Fig. 44 on the k -th cell ($1 \leq k \leq i-1$) and that shown in Fig. 46(a) on the i -th cell. We have

$$\begin{aligned} S_i^{(p)} &= \\ &= \frac{1}{2} \times \lambda_1^2 \lambda_2^2 A_{i-1}. \end{aligned} \quad (\text{G11})$$

The corresponding matrix is $\mathbf{S}_i^{R,(p)}$ in (4.64).

We derive the matrix $\mathbf{S}_i^{L,(p)}$. The graph on the j -th cell is shown in Fig. 46(b). Let $B_j^{(p)}$ and $C_j^{(p)}$ be the quantity defined by the right-hand side of (3.18) on the lattice Λ_j . The restriction for the sum is that the j -th cell is represented either by Fig. 44(d) for B_j and by (e) for C_j . The recursion relations are

$$A_j^{(p)} = 0 \quad (\text{G12})$$

$$\begin{aligned} B_j^{(p)} &= \\ &= -\frac{1}{2} \times 2 \times \lambda_1^2 S_{j-1} \end{aligned} \quad (\text{G13})$$

$$\begin{aligned} C_j^{(p)} &= \\ &= -\frac{1}{2} \times 2 \times \lambda_1^4 S_{j-1}. \end{aligned} \quad (\text{G14})$$

The corresponding matrix is $\mathbf{S}_j^{L,(p)}$ in (4.64). From the graph shown in Fig. 46(c) ((d)), the similar calculation leads the matrix $\mathbf{S}_i^{R,(d)}$ ($\mathbf{S}_j^{L,(d)}$) in (4.64).

4. Singlet-pair correlation function

The geometric representation of the expectation value is (3.11), where an example of the graph $V \cup V'$ is shown in Figs. 43(g) and (h) for (4.55)-(i) and (iii), respectively. In the Figures, a double solid (broken) line represent the operator $b_{i,j}^\dagger$ ($b_{k,l}$). We derive the transfer matrix $\mathbf{H}_n$ in (4.54). Let H_n be the quantity defined by a sum. The sum is taken over $V \cup V'$ on the lattice Λ_n such that the graph consists of loops shown in Fig. 44 on the k -th cell ($1 \leq k \leq i-1$) and graph shown in Fig. 47(a) on the l -th cell ($i < l \leq n$). The recursion relation is

$$\begin{aligned} H_n &= \\ &= \\ &= \lambda_1^2 \lambda_2^2 \mathbf{H}_{n-1}, \end{aligned} \quad (\text{G15})$$

and the corresponding matrix is $\mathbf{H}_n$ in (4.67).

We derive the matrix $\mathbf{H}_i^{R,(pp)}$. (We consider the case (4.55)-(i).) The graph on the i -th cell is shown in Fig. 47(b). Let $H_i^{(pp)}$ be the quantity defined by a sum. The sum is taken over $V \cup V'$ on the lattice Λ_i such that the graph consists of loops shown in Fig. 44 on the n -th cell ($1 \leq n \leq i-1$) and that shown in Fig. 47(b) on the i -th cell. The recursion relation is

$$\begin{aligned} H_i^{(pp)} &= \\ &= \lambda_1^2 \lambda_2^2 A_{i-1}. \end{aligned} \quad (\text{G16})$$

The corresponding matrix is $\mathbf{H}_i^{R,(pp)}$ in (4.67).

We derive the matrix $\mathbf{H}_k^{L,(pp)}$. (We consider the case (4.55)-(i).) We have two kinds of graphs on the k -th cell (Fig. 47(c) and (d)). Let $B_k^{(pp)}$ and $C_k^{(pp)}$ be the quantity defined by the right-hand side of (3.40) on the lattice Λ_k . The sum is taken over $V \cup V'$ with the restriction that the k -th cell is represented by Fig. 47(c) for $B_k^{(pp)}$ and (d) for $C_k^{(pp)}$. The recursion relations are

$$A_k^{(pp)} = 0 \quad (\text{G17})$$

$$\begin{aligned} B_k^{(pp)} &= \\ &= 2\lambda_1^2 H_{k-1} \end{aligned} \quad (\text{G18})$$

$$\begin{aligned} C_k^{(pp)} &= \\ &= 2\lambda_1^4 H_{k-1}, \end{aligned} \quad (\text{G19})$$

The corresponding matrix is $\mathbf{H}_k^{(pp)}$ in (4.67).

We consider the case (4.55)-(iii). The graphs on the i -th and the k -th cells are shown in Fig. 47(e) and (f), respectively. The similar calculation leads the matrices $\mathbf{H}_i^{R,(dp)}$ and $\mathbf{H}_k^{L,(dp)}$ in (4.67).

5. Correlation function $\langle c_{i,\sigma} c_{j,\sigma}^\dagger \rangle$

The geometric representation of the expectation value is (3.23), where an example of the graph $V \cup V'$ is shown in Fig. 43(i). We derive the matrix $\mathbf{G}_n$ in (4.54). A line is constructed by combining three kinds of cells shown in Figs. 48(a)-(c). To calculate the weight of the graph, it is necessary to use the procedure shown in Fig. 5(a). If we use the procedure m times for the graph with $2n$ bonds, we obtain a line with $2n - 2m$ bonds and m self-closed bonds. The weight of the line is $(-1)^{(2n-2m)/2} \times (-1)^m$, where the former power comes from (3.22) and the latter one comes from the procedure shown in Fig. 5(a). We use the same rule as that in (4.37) and the minus sign in Fig. 5(a) is automatically taken into account. Let D_n and E_n be the quantity defined by a sum. The sum is taken over $V \cup V'$ on the lattice Λ_n such that the graph consists of loops shown in Fig. 44 on the k -th cell ($1 \leq k \leq i-1$) and the graphs shown in Fig. 48(a)-(c) on the l -th cell ($i \leq l \leq n$). The restriction for the sum is that the n -th cell is represented by (a) or (b) for D_n and (c) for E_n . The recursion relations are

$$\begin{aligned} D_n &= \\ &= \\ &= -\lambda_1 \lambda_2 D_{n-1} - \lambda_1 \lambda_2 E_{n-1} - \lambda_1 \lambda_2^3 D_{n-1} \end{aligned} \quad (\text{G20})$$

$$\begin{aligned} E_n &= \\ &= \\ &= -\lambda_1^3 \lambda_2 D_{n-1} - \lambda_1^3 \lambda_2 E_{n-1}. \end{aligned} \quad (\text{G21})$$

The corresponding matrix is $\mathbf{G}_n$ in (4.70).

We derive the matrix $\mathbf{G}_i^{R,(p)}$. We have three kinds of graphs on the i -th cell (Fig. 48(d)-(f)). Let $D_i^{(p)}$ and $E_i^{(p)}$ be the quantity defined by a sum. The sum is taken over $V \cup V'$ on the lattice Λ_i such that the graph consists of loops shown in Fig. 44 on the k -th cell ($1 \leq k \leq i-1$) and those shown in Fig. 48(d)-(f) on i -th cell. The restriction for the sum is that the i -th cell is represented either by Fig. 48 (d) or (e) for $D_i^{(p)}$ and by (f) for $E_i^{(p)}$. The recursion relations are

$$\begin{aligned} D_i^{(p)} &= \\ &= -\lambda_1 \lambda_2 A_{i-1} - \lambda_1 \lambda_2 B_{i-1} - \lambda_1 \lambda_2^3 A_{i-1} \end{aligned} \quad (\text{G22})$$

$$\begin{aligned} E_i^{(p)} &= \\ &= -\lambda_1^3 \lambda_2 A_{i-1} - \lambda_1^3 \lambda_2 B_{i-1}. \end{aligned} \quad (\text{G23})$$

The corresponding matrix is $\mathbf{G}_i^{R,(p)}$ in (4.70).

We derive the matrix $\mathbf{G}_j^{L,(p)}$. We have four kinds of graphs on the j -th cell (Fig. 48(g)-(j)). Let $A_j^{(p)}$, $B_j^{(p)}$, and $C_j^{(p)}$ be the quantity defined by the right-hand side of (3.23) on the lattice Λ_j . The sum is taken over $V \cup V'$ such that the graph consists of loops shown in Fig. 44 on the k -th ($1 \leq k \leq i-1$) cells and a line shown in Fig. 48(a)-(c) on the l -th ($i \leq l \leq j-1$) cells. The restriction for the sum is that the j -th cell is represented by either by Fig. 48(g) for $A_j^{(p)}$, by (h) or (i) for $B_j^{(p)}$, and (j) for $C_j^{(p)}$. The recursion relations are

$$\begin{aligned} A_j^{(p)} &= \\ &= \lambda_2^2 D_{j-1} \end{aligned} \quad (\text{G24})$$

$$\begin{aligned}
B_j^{(p)} &= \\
&= \frac{1}{2}\lambda_1^2\lambda_2^2D_{j-1} + \lambda_1^2D_{j-1} + \lambda_1^2E_{j-1}
\end{aligned} \tag{G25}$$

$$\begin{aligned}
C_j^{(p)} &= \\
&= \lambda_1^4D_{j-1} + \lambda_1^4E_{j-1}.
\end{aligned} \tag{G26}$$

The coefficient $1/2$ in the first term in $B_i^{(p)}$ is to cancel weight 2 which is assigned at the left end of the line where we regard it as the end of a loop. The corresponding matrix is $\mathbf{G}_j^{L,(p)}$ in (4.70).

We derive the matrix $\mathbf{G}_i^{R,(d)}$. We have two kinds of graphs on the i -th cell (Fig. 48(k) and (l)). Let $D_i^{(d)}$ and $E_i^{(d)}$ be the quantity defined by a sum. The sum is taken over $V \cup V'$ on the lattice Λ_i such that the graph consists of loops shown in Fig. 44 on the k -th cell ($1 \leq k \leq i-1$) and that shown in Fig. 48(k) or (l) on i -th cell. The restriction for the sum is that the y -th cell is represented either by Fig. 48(k) for $D_y^{(d)}$ and by (l) for $E_y^{(d)}$. The recursion relations are

$$\begin{aligned}
D_i^{(d)} &= \\
&= -\lambda_1\lambda_2^2A_{i-1} - \lambda_1\lambda_2^2B_{i-1}
\end{aligned} \tag{G27}$$

$$\begin{aligned}
E_i^{(d)} &= \\
&= -\lambda_1^3A_{i-1} - 2\lambda_1^3B_{i-1} - \lambda_1^3C_{i-1}.
\end{aligned} \tag{G28}$$

The corresponding matrix is $\mathbf{G}_i^{R,(d)}$ in (4.70).

We derive the matrix $\mathbf{G}_j^{L,(d)}$. We have two kinds of graphs on the j -th cell (Fig. 48(m) and (n)). Let $A_j^{(d)}$ and $B_j^{(d)}$ be the quantity defined by the right-hand side of (3.23) on the lattice Λ_j . The sum is taken over $V \cup V'$ such that the graph consists of loops shown in Fig. 44 on the k -th ($1 \leq k \leq i-1$) cells and a line shown in Fig. 48(a)-(c) on the l -th ($i \leq l \leq j-1$) cells. The restriction for the sum is that the j -th cell is represented either by Fig. 48(m) for $A_j^{(d)}$ and by (n) for $B_j^{(d)}$. The recursion relations are

$$\begin{aligned}
A_j^{(d)} &= \\
&= -\lambda_2^3D_{j-1}
\end{aligned} \tag{G29}$$

$$\begin{aligned}
B_j^{(d)} &= \\
&= -\frac{1}{2}\lambda_1^2\lambda_2D_{j-1} - \frac{1}{2}\lambda_1^2\lambda_2E_{j-1}
\end{aligned} \tag{G30}$$

$$C_j^{(d)} = 0. \tag{G31}$$

The coefficient $1/2$ in $B_j^{(d)}$ is to cancel weight 2 which is assigned at the end of the line where we regard it as the end of a loop. The corresponding matrix is $\mathbf{G}_j^{L,(d)}$ in (4.70).

APPENDIX H: DERIVATION OF TRANSFER MATRICES FOR MODEL C

In Model C, the sites which is identified in the cell construction are d -sites and there is no site with four bonds in the geometric representation. Therefore, we do not need the procedures shown in Figs. 5, $m_j = 0$ in (3.11), (3.19), (3.24), (3.30), (3.37), and (3.40).

1. Norm of the ground state

The ground state is written by (3.3) geometrically, where an example of the valence-bond configuration V is shown in Fig. 49(a). The geometric representation of the norm is (3.11), where an example of the graph $V \cup V'$ is shown in Fig. 49(b). We first evaluate the contribution from a graph $V \cup V'$. It can be decomposed into the subgraphs $U_i \cup U'_i$ ($i = 1, 2, \dots, n(V \cup V')$).

We derive the matrix $\mathbf{T}_n$ in (4.82). A subgraph $U_i \cup U'_i$ is constructed by 27 kinds of cells shown in Fig. 50. The sum over the graph $V \cup V'$ is equivalent to that over all the combination of above 27 kinds of cells under the restriction that a d -site has at most two valence-bonds. We shall always take into account the restriction hereafter and it should be understood implicitly. Due to the restriction, we have to distinguish four cases with respect to two d -sites at left end of the lattice Λ_n : (i) they do not belong to valence bond; (ii) one of them belongs to two bonds; (iii) they each belong to two distinct bonds; (iv) they belong to a single degenerate loop. Let A_n - D_n be the quantity defined by the right-hand side of (3.6) on the lattice Λ_n . The sum is taken over $V \cup V'$ such that the graph consists of the subgraphs shown in Fig. 50. The restriction for the sum is that the n -th cell is classified by the condition (i) for A_n , (ii) for B_n , (iii) for C_n , and (iv) for D_n . They are represented diagrammatically

$$A_n = \quad (H1)$$

$$B_n = \quad (H2)$$

$$C_n = \quad (H3)$$

$$D_n = \quad (H4)$$

For the weight of a non-degenerate loop with $2n$ bonds, we assign the sign part $(-1)^{n-1}$ and the coefficient 2 separately. The loop belongs to n cells, since a cell has 2 bonds. We assign -1 to each $n - 1$ cells except for the cell in the right end of the loop. Accordingly, every recursion from C_{n-1} gives a minus sign. At left end of the loop, we assign the weight 2. Therefore, when we attach C_{n-1} to the n -th cell, we adopt the following rule. If the n -th cell satisfy the condition (i) or (ii), we make sure that the loop finishes on the n -th cell. Therefore, we assign coefficient -1×2 . In other cases, we assign coefficient -1 . The recursion relations are

$$\begin{aligned} A_n &= \\ &= 2A_{n-1} + 2\lambda^2 A_{n-1} + 2\lambda^2 B_{n-1} + 2\lambda^2 A_{n-1} + 2\lambda^2 B_{n-1} - 2\lambda^2 C_{n-1} - 2\lambda^2 C_{n-1} \\ &\quad + \lambda^4 A_{n-1} + \lambda^4 B_{n-1} + \lambda^4 B_{n-1} + \lambda^4 D_{n-1} \end{aligned} \quad (H5)$$

$$\begin{aligned} B_n &= \\ &= 2\lambda^2 A_{n-1} + 2\lambda^2 B_{n-1} + 2\lambda^2 B_{n-1} + 2\lambda^2 D_{n-1} + 2A_{n-1} + 2B_{n-1} + 2A_{n-1} + 2B_{n-1} \\ &\quad - 2C_{n-1} - 2C_{n-1} \end{aligned} \quad (H6)$$

$$\begin{aligned} C_n &= \\ &= \lambda^2 A_{n-1} + \lambda^2 B_{n-1} + \lambda^2 B_{n-1} + \lambda^2 D_{n-1} + A_{n-1} + B_{n-1} + A_{n-1} + B_{n-1} \\ &\quad - C_{n-1} - C_{n-1} \end{aligned} \quad (H7)$$

$$\begin{aligned} D_n &= \\ &= 2\lambda^2 A_{n-1} + 2\lambda^2 B_{n-1} + 2\lambda^2 B_{n-1} + 2\lambda^2 D_{n-1}, \end{aligned} \quad (H8)$$

where we assigned λ^{N_b} to the valence-bonds on the n -th cell as the contribution from $\lambda(U)\lambda(U')$. Here N_b is the number of the bonds which share a p -site. The corresponding matrix is

$$\begin{pmatrix} 2 + 4\lambda^2 + \lambda^4 & 4\lambda^2 + 2\lambda^4 & -4\lambda^2 & \lambda^4 \\ 4 + 2\lambda^2 & 4 + 4\lambda^2 & -4 & 2\lambda^2 \\ 2 + \lambda^2 & 2 + 2\lambda^2 & -2 & \lambda^2 \\ 2 & 4 & 0 & 2 \end{pmatrix}. \quad (\text{H9})$$

The initial and final vectors are $\vec{I} \equiv (A_0, B_0, C_0, D_0)^T = (1, 0, 0, 0)^T$ and $\vec{F} \equiv (A_N, B_N, C_N, D_N)^T = (1, 2, 0, 1)^T$, respectively. We find $B_n = 2C_n$. Therefore, the matrix is reduced to $\mathbf{T}_n$ in (4.82) with the base $(A_n, C_n, D_n)^T$. The corresponding initial and final vectors are $\vec{I} \equiv (A_0, C_0, D_0)^T = (1, 0, 0)^T$ and $\vec{F} \equiv (A_N, C_N, D_N)^T = (1, 4, 1)^T$.

2. Expectation value of the number operator

The geometric representation of the expectation value is (3.29), where an example of the graph $V \cup V'$ is shown in Fig. 49(c). We first derive the matrix $\mathbf{N}_i^{(p)}$. We have 9 kinds of graphs on the i -th cell (Fig. 50 (a1)-(a4), (a6), (b3), (b8), (c1), and (c2)). Let $A_i^{(p)}-D_i^{(p)}$ be the quantities classified by the conditions (i)-(iv) in Appendix H 1, respectively. When we attach $A_{i-1}^{(p)}-D_{i-1}^{(p)}$ to the i -th cell, we adopt the following rule to assign weight $(-1)^{l/2-1}$ to the valence bonds which share the p -site. When we attach C_{i-1} to the i -th cell, we assign coefficient -1 . For the degenerate loop on A_i and B_i , we assign weight 1. For the valence bonds on C_i , we assign coefficient $1/2$ to cancel weight 2 which is assigned at another end of the loop where we regard it as the end of a loop without the number operator. The recursion relations are

$$\begin{aligned} A_i^{(p)} &= \\ &= \lambda^2 A_{i-1} + \lambda^2 B_{i-1} + \lambda^2 A_{i-1} + \lambda^2 B_{i-1} - \lambda^2 C_{i-1} - \lambda^2 C_{i-1} + \lambda^4 A_{i-1} + \lambda^4 B_{i-1} \\ &\quad + \lambda^4 B_{i-1} + \lambda^4 D_{i-1} \end{aligned} \quad (\text{H10})$$

$$\begin{aligned} B_i^{(p)} &= \\ &= \lambda^2 A_{i-1} + \lambda^2 B_{i-1} + \lambda^2 B_{i-1} + \lambda^2 D_{i-1} \end{aligned} \quad (\text{H11})$$

$$\begin{aligned} C_i^{(p)} &= \\ &= \frac{1}{2} \lambda^2 A_{i-1} + \frac{1}{2} \lambda^2 B_{i-1} + \frac{1}{2} \lambda^2 B_{i-1} + \frac{1}{2} \lambda^2 D_{i-1} \end{aligned} \quad (\text{H12})$$

$$D_i^{(p)} = 0. \quad (\text{H13})$$

The corresponding matrix is

$$\begin{pmatrix} 2\lambda^2 + \lambda^4 & 2\lambda^2 + 2\lambda^4 & -2\lambda^2 & \lambda^4 \\ \lambda^2 & 2\lambda^2 & 0 & \lambda^2 \\ \frac{1}{2}\lambda^2 & \lambda^2 & 0 & \frac{1}{2}\lambda^2 \\ 0 & 0 & 0 & 0 \end{pmatrix}. \quad (\text{H14})$$

From the equality $B_n = 2C_n$, it is reduced to $\mathbf{N}_i^{(p)}$ in (4.83) with the base $(A_n, C_n, D_n)^T$.

We derive the matrix $\mathbf{N}_i^{(d)}$. We have 16 kinds of graphs on the i -th cell (Fig. 50 (a1)-(a3), (a5), (b1), (b2), (b4), (b6), (b7), (b10), and (c3)-(c8)). Let $A_i^{(d)}-D_i^{(d)}$ be the quantities classified by the conditions (i)-(iv) in Appendix H 1, respectively. From the same rule in the derivation of $\mathbf{N}_i^{(p)}$, the recursion relations are

$$A_i^{(d)} =$$

$$= A_{i-1} + \lambda^2 A_{i-1} + \lambda^2 B_{i-1} + \lambda^2 B_{i-1} - \lambda^2 C_{i-1} - \lambda^2 C_{i-1} + \frac{1}{2}\lambda^4 B_{i-1} + \frac{1}{2}\lambda^4 D_{i-1} \quad (\text{H15})$$

$$\begin{aligned} B_i^{(d)} &= \\ &= \lambda^2 B_{i-1} + \lambda^2 D_{i-1} + B_{i-1} + A_{i-1} + B_{i-1} - C_{i-1} - C_{i-1} \end{aligned} \quad (\text{H16})$$

$$\begin{aligned} C_i^{(d)} &= \\ &= \frac{1}{2}\lambda^2 B_{i-1} + \frac{1}{2}\lambda^2 D_{i-1} + \frac{1}{2}A_{i-1} + \frac{1}{2}B_{i-1} + \frac{1}{2}B_{i-1} - \frac{1}{2}C_{i-1} - \frac{1}{2}C_{i-1} \end{aligned} \quad (\text{H17})$$

$$\begin{aligned} D_i^{(d)} &= \\ &= \lambda^2 B_{i-1} + \lambda^2 D_{i-1}. \end{aligned} \quad (\text{H18})$$

The corresponding matrix is

$$\begin{pmatrix} 1 + \lambda^2 & 2\lambda^2 + \frac{1}{2}\lambda^4 & -2\lambda^2 & \frac{1}{2}\lambda^4 \\ 1 & 2 + \lambda^2 & -2 & \lambda^2 \\ \frac{1}{2} & 1 + \frac{1}{2}\lambda^2 & -1 & \frac{1}{2}\lambda^2 \\ 0 & 1 & 0 & 1 \end{pmatrix}. \quad (\text{H19})$$

From the equality $B_n = 2C_n$, it is reduced to $\mathbf{N}_i^{(d)}$ in (4.83).

3. Spin correlation function

The geometric representation of the expectation value is (3.18), where an example of the graph $V \cup V'$ is shown in Fig. 49(d). We evaluate the weight of the graph with the spin operators. Since there are two valence bonds in a cell, $d(i, j) = |i - j + 1| + l_e$ in (3.18) where l_e is the number of the bonds which are not on the n -th cell ($i \leq n \leq j$). (For example, $l_e = 6$ in Fig. 49(d)). We use the same rule in Appendix H 1 for C_n and that in H 3 for the assignment of the coefficient $\frac{1}{4}$. Accordingly, the coefficient $(-1)^{d(i, j)} \frac{1}{4}$ in (3.18) is automatically taken into account. We derive the matrix $\mathbf{S}_n$. We have four kinds of graphs on the n -th cell ($i + 1 \leq n \leq j - 1$) (Fig. 51(a)-(d)). Let S_n be the quantity defined by a sum. The sum is taken over $V \cup V'$ on the lattice Λ_n such that the graph consists of the cells shown in Fig. 50 on the k -th cell ($1 \leq k \leq i - 1$) and those shown in Fig. 51(a)-(d) on the l -th cell ($1 \leq l \leq n$). The recursion relation is

$$\begin{aligned} S_n &= \\ &= -S_{n-1} - S_{n-1}, \end{aligned} \quad (\text{H20})$$

and we have $\mathbf{S}_n = -2$.

We derive the matrix $\mathbf{S}_i^{R, (p)}$. We have two kinds of graphs on the i -th cell (Fig. 51(e) and (f)). The recursion relation is

$$\begin{aligned} S_i^{(p)} &= \\ &= \frac{1}{2} \times \lambda^2 A_{i-1} + \frac{1}{2} \times \lambda^2 B_{i-1} + \frac{1}{2} \times \lambda^2 B_{i-1} + \frac{1}{2} \times \lambda^2 D_{i-1}. \end{aligned} \quad (\text{H21})$$

The corresponding matrix is $(\frac{1}{2}\lambda^2, \lambda^2, \frac{1}{2}\lambda^2, 0)$ and is reduced to $\mathbf{S}_i^{R, (p)}$ in (4.86) with the base $(A_n, C_n, D_n)^T$.

We derive the matrix $\mathbf{S}_j^{L, (p)}$. We have two kinds of graph on the j -th cell (Fig. 51(g) and (h)). The recursion relation is

$$\begin{aligned} S_j^{(p)} &= \\ &= -\frac{1}{2} \times 2\lambda^2 S_{j-1} - \frac{1}{2} \times 2\lambda^2 S_{j-1}. \end{aligned} \quad (\text{H22})$$

The recursion relations to the $j + 1$ -th cell are

$$\begin{aligned} A_{j+1} &= \\ &= 2S'_j{}^{(p)} + 2\lambda^2 S'_j{}^{(p)} + 2\lambda^2 S'_j{}^{(p)} + \lambda^4 S'_j{}^{(p)} \end{aligned} \quad (\text{H23})$$

$$\begin{aligned} B_{j+1} &= \\ &= 2\lambda^2 S'_j{}^{(p)} + 2S'_j{}^{(p)} + 2S'_j{}^{(p)} \end{aligned} \quad (\text{H24})$$

$$\begin{aligned} C_{j+1} &= \\ &= \lambda^2 S'_j{}^{(p)} + S'_j{}^{(p)} + S'_j{}^{(p)} \end{aligned} \quad (\text{H25})$$

$$\begin{aligned} D_{j+1} &= \\ &= 2\lambda^2 S'_j{}^{(p)}, \end{aligned} \quad (\text{H26})$$

and the corresponding matrix is

$$\mathbf{S}'_{j+1}{}^{(p)} = \begin{pmatrix} 2 + 4\lambda^2 + \lambda^4 \\ 4 + 2\lambda^2 \\ 2 + \lambda^2 \\ 2 \end{pmatrix}. \quad (\text{H27})$$

A simple calculation leads that the product $\mathbf{S}'_{j+1}{}^{(p)} \mathbf{S}'_j{}^{(p)}$ is reduced to $\mathbf{T}_{j+1}{}^{(p)} \mathbf{S}_j{}^{(p)}$ with the base $(A_n, C_n, D_n)^T$ and we obtain $\mathbf{S}_j^{L,(p)}$ in (4.86).

We derive the matrix $\mathbf{S}_i^{R,(d)}$. We have six kinds of the graphs on the i -th cell (Fig. 51(i)-(n)). The recursion relation is

$$\begin{aligned} S_i^{(d)} &= \\ &= \frac{1}{2} \times A_{i-1} + \frac{1}{2} \times B_{i-1} - \frac{1}{2} \times C_{i-1} - \frac{1}{2} \times C_{i-1}. \end{aligned} \quad (\text{H28})$$

The corresponding matrix is $(\frac{1}{2}\lambda^2, \frac{1}{2}\lambda^2, -\lambda^2, 0)$ and is reduced to $\mathbf{S}_i^{R,(d)}$ in (4.86).

We derive the matrix $\mathbf{S}_i^{L,(d)}$. We have six kinds of graphs on the $j - 1$ -th cell (Fig. 51(o)-(t)). The recursion relation is

$$A_{j-1}^{(d)} = 0 \quad (\text{H29})$$

$$\begin{aligned} B_{j-1}^{(d)} &= \\ &= -\frac{1}{2} \times 2S_{j-2} - \frac{1}{2} \times 2S_{j-2} \end{aligned} \quad (\text{H30})$$

$$\begin{aligned} C_{j-1}^{(d)} &= \\ &= -\frac{1}{2} \times S_{j-2} - \frac{1}{2} \times S_{j-2} \end{aligned} \quad (\text{H31})$$

$$C_{j-1}^{(d)} = 0. \quad (\text{H32})$$

The corresponding matrix is $\mathbf{S}'_{j-1}{}^{(d)} = (0, -2, -1, 0)$. The recursion relations to the j -th cell are

$$\begin{aligned} A_j^{(d)} &= \\ &= 2\lambda^2 B_{j-1} - 2\lambda^2 C_{j-1} - \lambda^2 C_{j-1} \lambda^4 B_{j-1} \end{aligned} \quad (\text{H33})$$

$$\begin{aligned} B_j^{(d)} &= \\ &= 2\lambda^2 B_{j-1} + 2B_{j-1} - 2C_{j-1} - 2C_{j-1} \end{aligned} \quad (\text{H34})$$

$$\begin{aligned} C_j^{(d)} &= \\ &= \lambda^2 B_{j-1} + B_{j-1} - C_{j-1} - C_{j-1} \end{aligned} \quad (\text{H35})$$

$$\begin{aligned} D_j^{(d)} &= \\ &= 2\lambda^2 B_{j-1}, \end{aligned} \quad (\text{H36})$$

and the corresponding matrix is

$$\mathbf{S}'^{(d)}_j = \begin{pmatrix} 0 & 2\lambda^2 + \lambda^4 & -4\lambda^2 & 0 \\ 0 & 2 + 2\lambda^2 & -4 & 0 \\ 0 & 1 + \lambda^2 & -2 & 0 \\ 0 & 2 & 0 & 0 \end{pmatrix}. \quad (\text{H37})$$

A simple calculation leads that the product $\mathbf{S}'^{(d)}_j \mathbf{S}'^{(d)}_{j-1}$ is reduced to $\mathbf{S}^{(d)}_j \mathbf{S}_{j-1}$ with the base $(A_n, C_n, D_n)^T$. We obtain $\mathbf{S}^{L,(d)}_j$ in (4.86).

4. Singlet-pair correlation function

The geometric representation of the expectation value is (3.11), where an example of the graph $V \cup V'$ is shown in Figs. 49(e) and (f) for (4.55)-(i) and (iii), respectively. We derive the matrix $\mathbf{H}_n$. On the n -th cell we have one kind of graph (Fig. 52(a)). Let H_n be the quantity defined by a sum. The sum is taken over $V \cup V'$ on the lattice Λ_n such that the graph consists of the cells shown in Fig. 50 on the k -th cell ($1 \leq k \leq i-1$) and that shown in Fig. 52(a) on the l -th cell ($i \leq l \leq n$). It is represented diagrammatically

$$H_n =, \quad (\text{H38})$$

and the recursion relation is

$$\begin{aligned} H_n &= \\ &= 2H_{n-1}. \end{aligned} \quad (\text{H39})$$

Therefore, we obtain $\mathbf{H}_n = 2$.

We derive the matrix $\mathbf{H}^{R,(p)}_i$. (We consider the case (4.55)-(i).) We have one kind of graph on the i -th cell (Fig. 52(b)). The recursion relation is

$$\begin{aligned} H^{(p)}_i &= \\ &= \lambda^2 A_{i-1} + \lambda^2 B_{i-1} + \lambda^2 B_{i-1} + \lambda^2 D_{i-1}. \end{aligned} \quad (\text{H40})$$

The corresponding matrix is $\lambda^2(1, 2, 1, 0)$ and is reduced to $\mathbf{H}^{R,(p)}_i$ in (4.86) with the base $(A_n, C_n, D_n)^T$.

We derive the matrix $\mathbf{H}^{L,(p)}_{k+1}$. (We consider the case (4.55)-(i).) We have one kind of graph on the k -th cell (52(c)). The recursion relation is

$$\begin{aligned} H'^{(p)}_k &= \\ &= -2\lambda^2 H_{k-1}. \end{aligned} \quad (\text{H41})$$

The recursion relations to the $k+1$ -th cell are

$$\begin{aligned} A_{k+1} &= \\ &= 2H'^{(p)}_k + 2\lambda^2 H'^{(p)}_k + 2\lambda^2 H'^{(p)}_k + \lambda^4 H'^{(p)}_k \end{aligned} \quad (\text{H42})$$

$$\begin{aligned} B_{k+1} &= \\ &= 2\lambda^2 H'^{(p)}_k + 2H'^{(p)}_k + 2H'^{(p)}_k \end{aligned} \quad (\text{H43})$$

$$\begin{aligned} C_{k+1} &= \\ &= \lambda^2 H'^{(p)}_k + H'^{(p)}_k + H'^{(p)}_k \end{aligned} \quad (\text{H44})$$

$$\begin{aligned} D_{k+1} &= \\ &= 2\lambda^2 H'^{(p)}_k. \end{aligned} \quad (\text{H45})$$

Therefore, we have $\mathbf{H}'_{k+1}^{(p)} = \mathbf{S}'_{k+1}^{(p)}$. A simple calculation leads that the product $\mathbf{H}'_{k+1}^{(p)} \mathbf{H}_k^{(p)}$ is reduced to $\mathbf{H}_{k+1}^{L,(p)} \mathbf{H}_k$ with the base $(A_n, C_n, D_n)^T$. We obtain $\mathbf{H}_{k+1}^{L,(p)}$ in (4.88).

We derive the matrix $\mathbf{H}_i^{R,(dp)}$. (We consider the case (4.55)-(iii).) We have one kind of graph on the i -th cell (Fig. 52(d)). The transfer matrix is obtained by replacing the graph in (H40) by Fig. 52(d). We find $\mathbf{H}_i^{(dp)} = \mathbf{H}_i^{(p)}$ and obtain $\mathbf{H}_i^{R,(dp)}$ in (4.88). Similarly, we find $\mathbf{H}'_{k+1}^{(dp)} = \mathbf{H}'_{k+1}^{(p)}$ using the graph Fig. 52(e). We obtain $\mathbf{H}_{k+1}^{L,(d)}$ in (4.88).

5. Correlation function $\langle c_{i,\sigma} c_{j,\sigma}^\dagger \rangle$

The geometric representation of the expectation value is (3.23), where an example of the graph $V \cup V'$ for $\langle c_{i,\sigma}^p c_{j,\sigma}^{p\dagger} \rangle$ is shown in Fig. 49(g). For a line, we have 12 kinds of graphs on the n -th cell ($i+1 \leq n \leq j-1$) (Fig. 53). We distinguish four cases with respect to two d -sites at left end of the lattice Λ_n : (i) the upper site belongs to a line and is an end of the line; (ii) the lower site belongs to a line and is an end of the line; (iii) both sites belong to a line and the lower site is an end of the line; (iv) both sites belong to a line and the upper site is an end of the line. Let K_n - N_n be the quantity defined by a sum. The sum is taken over $V \cup V'$ on the lattice Λ_n such that the graph consists of loops shown in Fig. 50 on the k -th cell ($1 \leq k \leq i-1$) and a line shown in Fig. 53 on the l -th cell ($i \leq k \leq n$). The restriction for the sum is that the n -th cell is classified to (i) for K_n , (ii) for L_n , (iii) for M_n , (iv) for N_n . They are represented diagrammatically

$$K_n = \quad (H46)$$

$$L_n = \quad (H47)$$

$$M_n = \quad (H48)$$

$$N_n = . \quad (H49)$$

We use the same rule as that in (4.37), when we attach K_{n-1} - N_{n-1} to the n -th cell. The recursion relations are

$$\begin{aligned} K_n &= \\ &= -L_{n-1} - K_{n-1} - \lambda^2 L_{n-1} - \lambda^2 M_{n-1} - \lambda^2 K_{n-1} - \lambda^2 N_{n-1} \end{aligned} \quad (H50)$$

$$\begin{aligned} L_n &= \\ &= -K_{n-1} - L_{n-1} - \lambda^2 K_{n-1} - \lambda^2 N_{n-1} - \lambda^2 L_{n-1} - \lambda^2 M_{n-1} \end{aligned} \quad (H51)$$

$$\begin{aligned} M_n &= \\ &= -L_{n-1} - M_{n-1} - K_{n-1} - N_{n-1} \end{aligned} \quad (H52)$$

$$\begin{aligned} N_n &= \\ &= -K_{n-1} - N_{n-1} - L_{n-1} - M_{n-1}. \end{aligned} \quad (H53)$$

The corresponding matrix is

$$- \begin{pmatrix} 1 + \lambda^2 & 1 + \lambda^2 & \lambda^2 & \lambda^2 \\ 1 + \lambda^2 & 1 + \lambda^2 & \lambda^2 & \lambda^2 \\ 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 \end{pmatrix}. \quad (H54)$$

From the equalities $K_n = L_n$ and $M_n = N_n$, it is reduced to $\mathbf{G}_n$ in (4.90).

We derive $\mathbf{G}_i^{R,(p)}$. We have eight kinds of graphs on the i -th cell (Fig. 53(pk1)-(pm6)). Let $K_i^{(p)}$ and $M_i^{(p)}$ be the quantity defined by a sum. The sum is taken over $V \cup V'$ on the lattice Λ_i such that the graph consists of the cells shown in Fig. 50 on the k -th cell ($1 \leq k \leq i-1$). The

restriction for the sum is that the i -th cell is represented by Fig. 53(pk1) or (pk2) for K_n and by (pm1)-(pm6) for M_n . They are represented diagrammatically

$$K_i^{(p)} = = \quad (H55)$$

$$M_i^{(p)} = = . \quad (H56)$$

We use the same rule described above (4.37) except for that for C_i . When we attach the graph C_{i-1} to the i -th cell, We assign one more coefficient -1 to cancel the coefficient $+1$ at the beginning of the line where we regarded the right end of the line as that of a loop. The recursion relations are

$$\begin{aligned} K_i^{(p)} &= \\ &= -\lambda A_{i-1} - \lambda B_{i-1} - \lambda B_{i-1} - \lambda D_{i-1} \end{aligned} \quad (H57)$$

$$\begin{aligned} M_i^{(p)} &= \\ &= -\lambda A_{i-1} - \lambda B_{i-1} - \lambda A_{i-1} - \lambda B_{i-1} + \lambda C_{i-1} + \lambda C_{i-1}. \end{aligned} \quad (H58)$$

The corresponding matrix is

$$- \begin{pmatrix} \lambda & 2\lambda & 0 & \lambda \\ 2\lambda & 2\lambda & -2\lambda & 0 \end{pmatrix}, \quad (H59)$$

and is reduced to $\mathbf{G}_i^{R,(p)}$ in (4.90) with the base $(A_n, C_n, D_n)^T$.

We derive $\mathbf{G}_j^{L,(p)}$. We have ten kinds of graphs on the j -th cell (Fig. 53(a1)-(c4)). Let $A_j^{(p)}$, $B_j^{(p)}$, and $C_j^{(p)}$ be the quantity defined by the right-hand side of (3.23) on the lattice Λ_j . The sum is taken over the graph $V \cup V'$ such that the graph consists of loops shown in Fig. 50 on the k -th cell ($1 \leq k \leq i-1$) and a line shown in Fig. 53 (g1)-(g12) on the l -th cell ($i \leq l \leq j$). The restriction for the sum is that the j -th cell is represented by either Fig. 53(pa1) or (pa2) for $A_j^{(p)}$, (pb1)-(pb4) for $B_j^{(p)}$, and (pc1)-(pc4) for $C_j^{(p)}$. They are represented diagrammatically

$$A_j^{(p)} = \quad (H60)$$

$$B_j^{(p)} = = \quad (H61)$$

$$C_j^{(p)} = = . \quad (H62)$$

When we attach the $j-1$ -th graph to the j -th cell in $C^{(p)}$, we assign coefficient $1/2$ to cancel weight 2 which is assigned at end of the line where we regard it as the left end of a loop. The recursion relations are

$$\begin{aligned} A_j^{(p)} &= \\ &= -\lambda K_{j-1} - \lambda K_{j-1} \end{aligned} \quad (H63)$$

$$\begin{aligned} B_j^{(p)} &= \\ &= -\lambda K_{j-1} - \lambda M_{j-1} - \lambda K_{j-1} - \lambda M_{j-1} \end{aligned} \quad (H64)$$

$$\begin{aligned} C_j^{(p)} &= \\ &= -\frac{1}{2}\lambda K_{j-1} - \frac{1}{2}\lambda M_{j-1} - \frac{1}{2}\lambda K_{j-1} - \frac{1}{2}\lambda M_{j-1} \end{aligned} \quad (H65)$$

$$D_j^{(p)} = 0 \quad (H66)$$

The corresponding matrix is

$$- \begin{pmatrix} 2\lambda & 0 \\ 2\lambda & 2\lambda \\ \lambda & \lambda \\ 0 & 0 \end{pmatrix}, \quad (H67)$$

and is reduced to $\mathbf{G}_j^{L,(p)}$ in (4.90).

We derive $\mathbf{G}_i^{R,(d)}$. Let $A_i^{(d)}$ - $C_i^{(d)}$ be the quantity defined by a sum. The sum is taken over $V \cup V'$ on the lattice Λ_i such that the graph consists of the cells shown in Fig. 50 on the k -th cell ($1 \leq k \leq i-1$). The restriction for the sum is that the i -th cell is classified by the condition (i) for $A_i^{(p)}$ (ii) for $B_i^{(d)}$, and (iii) for $C_i^{(d)}$ in Appendix H1, respectively. They are represented diagrammatically

$$A_i^{(d)} = \quad (H68)$$

$$B_i^{(d)} = \quad (H69)$$

$$C_i^{(d)} = . \quad (H70)$$

After a simple calculation we find $A_i^{(d)} = A_i$, $B_i^{(d)} = B_i$, $C_i^{(d)} = C_i$, and $D_i = 0$. We use the same rule for the derivation of $\mathbf{G}_i^{R,(p)}$. Using the graph shown in Fig. 53(dk1)-(dn2)), the recursion relations to the $i+1$ -th cell are

$$\begin{aligned} K_{i+1} &= \\ &= -\lambda^2 A_i^{(d)} - \lambda^2 B_i^{(d)} - C_i^{(d)} - A_i^{(d)} \end{aligned} \quad (H71)$$

$$\begin{aligned} L_{i+1} &= \\ &= -\lambda^2 A_i^{(d)} - \lambda^2 B_i^{(d)} - C_i^{(d)} - A_i^{(d)} \end{aligned} \quad (H72)$$

$$\begin{aligned} M_{i+1} &= \\ &= -A_i^{(d)} - B_i^{(d)} + C_i^{(d)} \end{aligned} \quad (H73)$$

$$\begin{aligned} N_{i+1} &= \\ &= -A_i^{(d)} - B_i^{(d)} + C_i^{(d)}. \end{aligned} \quad (H74)$$

The corresponding matrix is

$$- \begin{pmatrix} 1 + \lambda^2 & \lambda^2 & \lambda^2 & 0 \\ 1 + \lambda^2 & \lambda^2 & \lambda^2 & 0 \\ 1 & 1 & -1 & 0 \\ 1 & 1 & -1 & 0 \end{pmatrix}. \quad (H75)$$

From the equalities $K_{i+1} = L_{i+1}$ and $M_{i+1} = N_{i+1}$, we obtain $\mathbf{G}_i^{R,(d)}$ in (4.90).

We derive $\mathbf{G}_j^{L,(p)}$. Let $K_j^{(d)}$, $L_j^{(d)}$, and $N_j^{(d)}$ be the quantity defined by the right-hand side of (3.24) on the lattice Λ_j . The sum is taken over the graph $V \cup V'$ such that the graph consists of loops shown in Fig. 50 on the k -th cell ($1 \leq k \leq i-1$) and a line shown in Fig. 53 (g1)-(g12) on the l -th cell ($i \leq l \leq j$). The restriction for the sum is that the j -th cell is classified by the condition (i) for $K_i^{(p)}$ (ii) for $L_i^{(d)}$, and (iv) for $N_i^{(d)}$ in Appendix H5, respectively. They are represented diagrammatically

$$K_j^{(d)} = \quad (H76)$$

$$L_j^{(d)} = \quad (H77)$$

$$N_j^{(d)} = . \quad (H78)$$

We use the same rule in the derivation of $\mathbf{G}_j^{L,(p)}$. Using the graph shown in Fig. 53(da1)-(dd1)), the recursion relations are

$$\begin{aligned} A_{j+1} &= \\ &= 2\lambda^2 K_j^{(d)} - \lambda^2 L_j^{(d)} + \lambda^4 K_j^{(d)} + \lambda^4 N_j^{(d)} \end{aligned} \quad (H79)$$

$$\begin{aligned}
B_{j+1} &= \\
&= 2\lambda^2 K_j^{(d)} + 2\lambda^2 N_j^{(d)} + 2K_j^{(d)} - L_j^{(d)}
\end{aligned} \tag{H80}$$

$$\begin{aligned}
C_{j+1} &= \\
&= \lambda^2 K_j^{(d)} + \lambda^2 N_j^{(d)} + K_j^{(d)} - \frac{1}{2} L_j^{(d)}
\end{aligned} \tag{H81}$$

$$\begin{aligned}
D_{j+1} &= \\
&= 2K_j^{(d)} + 2N_j^{(d)}.
\end{aligned} \tag{H82}$$

The corresponding matrix is

$$\begin{pmatrix} 2\lambda^2 + \lambda^4 & -\lambda^2 & 0 & \lambda^4 \\ 2 + 2\lambda^2 & -1 & 0 & 2\lambda^2 \\ 1 + \lambda^2 & -\frac{1}{2} & 0 & \lambda^2 \\ 2 & 0 & 0 & 2 \end{pmatrix}. \tag{H83}$$

From the equality $B_n = 2C_n$, the matrix is reduced to $\mathbf{G}_j^{L,(p)}$ in (4.90) with the base $(A_n, C_n, D_n)^T$.

FIGURES

FIG. 1. The correspondence between the sites $x (\in \Lambda_N)$ and $r (\in C_n)$.

FIG. 2. Diagrammatic representation of the valence bonds. The solid (broken) line represents a valence bond in the ket (bra). We distinguish four kinds of bonds and call them as non-closed “ket-bond” (a), non-closed “bra-bond” (b), self-closed “ket-bond” (c), and self-closed “bra-bond” (d). A d -site with $U = \infty$ is denoted by a solid circle, and a p -site with $U = 0$ is denoted by a circle.

FIG. 3. Examples of valence-bond configurations (a) V , (b) V' , and (c) their overlap $V \cup V'$. The lattice is constructed from a cell with one d -site and four p -sites. P -sites in adjacent cells actually is a single p -site. The thin broken lines represent hoppings of electrons. The graph $V \cup V'$ is factorized into four connected subgraphs (d)-(g).

FIG. 4. Diagrammatic representation of the identity $b_{x,y}^\dagger b_{y,z}^\dagger = -b_{y,y}^\dagger b_{x,z}^\dagger$.

FIG. 5. Examples of the elimination of a p -site with four bonds, which exhaust all the cases. For (a), we apply the identity $b_{x,y}^\dagger b_{y,z}^\dagger = -b_{y,y}^\dagger b_{x,z}^\dagger$ once. For (b) and (c), we apply it two times.

FIG. 6. Example of the procedure of the elimination of the p -sites with four bonds. We have self-closed bonds (a), degenerate loop (b), and non-degenerate loop (c) after the procedure.

FIG. 7. Example of graph where sites x and y belong to a single subgraph.

FIG. 8. (a), (b) Type (i) configuration. (c), (d) Type (ii) configuration.

FIG. 9. Diagrammatic representation of the identity $c_{x,\sigma}^\dagger b_{x,y}^\dagger = -c_{y,\sigma}^\dagger b_{y,y}^\dagger$ (d). A pentagon represents the operator $c_{x,\sigma}^\dagger$.

FIG. 10. (a) and (b) Examples of the procedure of the elimination of type (ii) configuration. (c) Example of a line.

FIG. 11. (a) Type (i) configuration. (b) Type (ii) configuration.

FIG. 12. (a) Type (i) configuration. (b) Type (ii) configuration. (c) Type (iii) configuration. (d) Type (iv) configuration.

FIG. 13. Model A. (a) A cell compose of two d -sites and one p -site. (b) The lattice constructed from the cell with cell labelings. (c) The same lattice as (b) drawn differently with unit cell labelings.

FIG. 14. The dispersion relations E_+ and E_- . (a) The parameters are $\lambda_1 = \lambda_2 = 1$. (b) The parameters are $\lambda_1 = \lambda_2 = \frac{1}{\sqrt{2}}$.

FIG. 15. Examples of configuration of the valence-bonds in the geometric representation for (a) the ground state, (b) the norm of the ground state, (c) the expectation value of the number operator $n_{i,\sigma}^p$, (d) the density correlation function for p -sites, (e) the correlation functions $\langle c_{i,\sigma}^p c_{j,\sigma}^{p\dagger} \rangle$ and (f) the correlation function $\langle c_{i,\sigma}^d c_{j,\sigma}^{d\dagger} \rangle$.

FIG. 16. Configurations of the valence-bonds on a cell. The weights including the contributions from $\lambda(U)\lambda(U')$ are (a) $2\lambda_2^2$, (b) 1, (c) $2\lambda_1^2\lambda_2^2$, and (d) $2\lambda_1^2$.

FIG. 17. Configurations of the valence-bonds on the i -th cell in the geometric representation for $\langle n_{i,\sigma}^p \rangle$ (a)-(c) and $\langle n_{i,\sigma}^d \rangle$ (d) and (e). The weights including the contributions from $\lambda(U)\lambda(U')$ are (a) λ_2^2 , (b) 1, (c) λ_1^2 , (d) λ_2^2 , (e) $\lambda_1^2\lambda_2^2$, and (f) λ_1^2 .

FIG. 18. Occupation on the p -site (a) and the d -site (b) for $\lambda_2 = 0.1, 0.5, 1, 2$, and 4 (solid line) and $\lambda_2 = \lambda_1$ (broken line).

FIG. 19. Density correlation function for the nearest-neighbor p -sites for $\lambda_2 = 0.5, 1, 2, 4$, and 8 (solid line) and $\lambda_2 = \lambda_1$ (broken line).

FIG. 20. Density correlation function for the nearest-neighbor d -sites for $\lambda_2 = 0.5, 1, 2$, and 4 (solid line) and $\lambda_2 = \lambda_1$ (broken line).

FIG. 21. Configurations of the valence-bonds on the n -th cell (a) ($i+1 \leq n \leq j-1$) in the geometric representation for $\langle c_{i,\sigma}^\alpha c_{j,\sigma}^{\alpha\dagger} \rangle$. Those on the i -th cell (b) and (c), and the j -th cell (d) and (e) for $\alpha = p$, and on the i -th cell (f) and the $j-1$ -th cell (g) for $\alpha = d$. The contributions from $\lambda(U)\lambda(U')$ are (a) $\lambda_1\lambda_2$, (b) λ_1 , (c) $\lambda_1\lambda_2^2$, (d) λ_2 , (e) $\lambda_1^2\lambda_2$, (f) $\lambda_1\lambda_2$, and (g) $\lambda_1\lambda_2$.

FIG. 22. Momentum distribution functions for the p -site (a) and the d -site for (b) for $\lambda_1 = \lambda_2 = 0.1, 0.2, 0.5, 1, 2$, and 100.

FIG. 23. Momentum distribution functions for the p -site (a) and the d -site (b) for $\lambda_2 = 0.01, 0.1, 0.5, 1, 2$, and 100 with $\lambda_1 = 1$.

FIG. 24. Correlation lengths of the correlation function $\langle c_{i,\sigma} c_{j,\sigma}^\dagger \rangle$ (a) and that of the density correlation function (b) for $\lambda_1 = \lambda_2$.

FIG. 25. Model B. (a) A cell compose of two p -sites and one d -site. (b) The lattice constructed from the cell with cell labelings.

FIG. 26. The dispersion relations E_+ and E_- . The parameters are $\lambda_1 = \lambda_2 = 1$.

FIG. 27. Occupation on the p -site (a) and the d -site (b) for $\lambda_2 = 1, 2, 4$, and 8 (solid line) and $\lambda_2 = \lambda_1$ (broken line).

FIG. 28. Density correlation function for the nearest-neighbor p -sites for $\lambda_2 = 0.5, 1, 2, 4$, and 8 (solid line) and $\lambda_2 = \lambda_1$ (broken line).

FIG. 29. Density correlation function for the nearest-neighbor d -sites for $\lambda_2 = 0.5, 1, 2, 4$, and 8 (solid line) and $\lambda_2 = \lambda_1$ (broken line).

FIG. 30. Spin correlation functions for the nearest-neighbor p -sites (a) for $\lambda_2 = 2, 4$, and 8 (solid line), d -sites (b) for $\lambda_2 = 1, 2$, and 4 (solid line), and p - and d -sites (c) for $\lambda_2 = 1, 2, 4$, and 8 (solid line). The broken lines are for $\lambda_2 = \lambda_1$.

FIG. 31. Singlet-pair correlation function for the nearest-neighbor p -sites for $\lambda_2 = 1, 2, 4$, and 8 (solid line) and $\lambda_2 = \lambda_1$ (broken line).

FIG. 32. Momentum distribution functions for the p -site (a) and the d -site (b) for $\lambda_1 = \lambda_2 = 0.01, 1, 10$, and 100 .

FIG. 33. Momentum distribution functions for the p -site (a) and the d -site (b) for $\lambda_2 = 0.01, 0.1, 1, 5$, and 10 with $\lambda_1 = 1$.

FIG. 34. Correlation lengths of the correlation function $\langle c_{i,\sigma} c_{j,\sigma}^\dagger \rangle$ (a), that of the density correlation function (b), and that of the spin and the singlet-pair correlation functions (c) for $\lambda_1 = \lambda_2$.

FIG. 35. Model C. (a) A cell compose of one p -sites and four d -site. (b) The lattice constructed from the cell with cell labelings.

FIG. 36. The dispersion relations E_1 , E_2 , and E_3 . The parameters are (a) $\lambda = 1$, (b) $\lambda = \sqrt{2}$, and (c) $\lambda = 2$.

FIG. 37. Occupation on the p -site (a) and the d -site (b).

FIG. 38. Density correlation functions for the nearest-neighbor p -sites (a) and d -sites (b).

FIG. 39. Spin correlation functions for the nearest-neighbor p -sites (a), p - and d -sites (b), and d -sites (c).

FIG. 40. Singlet-pair correlation function for the nearest-neighbor p -sites.

FIG. 41. Momentum distribution functions for the p -site (a) and the d -site (b) for $\lambda = 0.1, 0.5, 1, 2$, and 10 .

FIG. 42. Correlation lengths of the correlation function $\langle c_{i,\sigma} c_{j,\sigma}^\dagger \rangle$ (a), that of the density correlation function (b), and that of the spin and the singlet-pair correlation functions (c).

FIG. 43. (a) The same lattice as Fig. 25(b) drawn differently with unit cell labelings. Examples of the configurations of the valence-bonds in the geometric representation for (b) the ground state, (c) the norm of the ground state, (d) the norm of the ground state after the elimination of p -sites with four bonds, (e) the expectation value of the number operator $n_{i,\sigma}^p$, (f) the spin correlation function $\langle S_i^{z,p} S_j^{z,p} \rangle$, (g) the singlet-pair correlation functions $\langle b_{i,i}^\dagger b_{k,k} \rangle$ and (h) $\langle b_{i,j}^\dagger b_{k,l} \rangle$, and (i) the correlation function $\langle c_{i,\sigma}^p c_{j,\sigma}^{p\dagger} \rangle$. (j) Examples of the loops extending over more than two cells.

FIG. 44. Configurations of the valence-bond on a cell. The contributions from $\lambda(U)\lambda(U')$ are (a) λ_2^2 , (b) λ_2^4 , (c) $\lambda_1^2\lambda_2^2$, (d) λ_1^2 , and (e) λ_1^4 .

FIG. 45. Configurations of the valence-bonds on the i -th cell in the geometric representation for $\langle n_{i,\sigma}^p \rangle$ (a)-(d) and of $\langle n_{i,\sigma}^d \rangle$ (e)-(g). The contributions from $\lambda(U)\lambda(U')$ are (a) λ_2^2 , (b) λ_2^4 , (c) $\lambda_1^2\lambda_2^2$, (d) λ_1^4 , (e) λ_2^2 , (f) $\lambda_1^2\lambda_2^2$, and (g) λ_1^2 .

FIG. 46. Configurations of the valence-bonds on the i -th cell (a) and the $j-1$ -th cell (b) in the geometric representation for $\langle S_i^{z,p} S_j^{z,p} \rangle$ and on the i -th cell (c) and the j -th cell (d) for $\langle S_i^{z,d} S_j^{z,d} \rangle$. The contributions from $\lambda(U)\lambda(U')$ are (a) $\lambda_1^2\lambda_2^2$, (b) $\lambda_1^2\lambda_2^2$, (c) λ_1^2 , and (d) λ_2^2 .

FIG. 47. Configurations of the valence-bonds on the n -th cell (a) ($i+1 \leq n \leq j-1$) in the geometric representation for the singlet-pair correlation functions. Those on the i -th cell (b) and the k -th cell (c) and (d) for $\langle b_{i,i}^\dagger b_{k,k} \rangle$, and on the i -th cell (e) and the k -th cell (f) in $\langle b_{i,j}^\dagger b_{k,l} \rangle$. The contributions from $\lambda(U)\lambda(U')$ are (a) $\lambda_1^2\lambda_2^2$, (b) $\lambda_1^2\lambda_2^2$, (c) λ_1^2 , (d) λ_1^4 , (e) $\lambda_1^2\lambda_2$, and (f) $\lambda_1\lambda_2^2$.

FIG. 48. Configurations of the valence-bonds on the n -th cell (a)-(c) ($i+1 \leq n \leq j-1$) in the geometric representation for $\langle c_{i,\sigma}^\alpha c_{j,\sigma}^{\alpha\dagger} \rangle$. Those on the i -th cell (d)-(f) and the j -th cell (g)-(j) for $\alpha = p$, and on the i -th cell (k) and (l) and on the j -th cell (m) and (n) for $\alpha = d$. The contributions from $\lambda(U)\lambda(U')$ are (a) $\lambda_1\lambda_2$, (b) $\lambda_1^3\lambda_2$, (c) $\lambda_1\lambda_2^3$, (d) $\lambda_1\lambda_2$, (e) $\lambda_1\lambda_2^3$, (f) $\lambda_1^3\lambda_2$, (g) λ_2^2 , (h) $\lambda_1^2\lambda_2^2$, (i) λ_1^2 , (j) λ_1^4 , (k) $\lambda_1\lambda_2^2$, (l) λ_1^3 , (m) λ_2^3 , and (n) $\lambda_1^2\lambda_2$.

FIG. 49. Examples of the configurations of the valence-bonds in the geometric representation for (a) the ground state, (b) the norm of the ground state, (c) the expectation value of the number operator $n_{i,\sigma}^p$, (d) the spin correlation function $\langle S_i^{z,p} S_j^{z,d} \rangle$, the singlet-pair correlation functions (e) $\langle b_{i,i}^\dagger b_{k,k} \rangle$ and (f) $\langle b_{i,j}^\dagger b_{k,l} \rangle$, and (g) the correlation function $\langle c_{i,\sigma}^p c_{j,\sigma}^{p\dagger} \rangle$.

FIG. 50. Configurations of the valence-bonds on a cell. The contributions from $\lambda(U)\lambda(U')$ are 1 for the valence bonds which do not belong to a p -site, λ^2 for the valence bonds which belong to a p -site (except for (a6)), and λ^4 for (a6).

FIG. 51. Configurations of the valence-bonds on the n -th cell (a)-(d) ($i+1 \leq n \leq j-1$) in the geometric representation for the spin correlation functions. Those on the i -th cell (e) and (f) and on the j -th cell (g) and (h) for $\langle S_i^{z,p} S_j^{z,p} \rangle$, and on the i -th cell (i)-(n) and on the j -th cell (o)-(t) for $\langle S_i^{z,d} S_j^{z,d} \rangle$.

FIG. 52. Configurations of the valence-bonds on the n -th cell (a) ($i + 1 \leq n \leq j - 1$) in the geometric representation for the singlet-pair correlation functions. Those on the i -th cell (b) and the k -th cell (c) for $\langle b_{i,i}^\dagger b_{k,k} \rangle$, and on the i -th cell (d) and the u -th cell (e) for $\langle b_{i,j}^\dagger b_{k,l} \rangle$.

FIG. 53. Configurations of the valence-bonds on the n -th cell ($i + 1 \leq n \leq j - 1$) in the geometric representation for the correlation function $\langle c_{i,\sigma} c_{j,\sigma}^\dagger \rangle$. Those on the i -th cell (pk1)-(pm6) and on the j -th cell (pa1)-(pc4) for $\langle c_{i,\sigma}^p c_{j,\sigma}^{p\dagger} \rangle$, and on the i -th cell (dk1)-(dn2) and on the j -th cell (da1)-(dd2) for $\langle c_{i,\sigma}^d c_{j,\sigma}^{d\dagger} \rangle$,

TABLES

TABLE I. The cell construction of the models in Refs. [1,2,3,4,5]. Parameters (a) are those of Refs. [1,2,3]. When we choose λ_j 's, which are defined in the cell, those in (b), the parameters (c) represents those in column (a). The model with boundary condition in the last column satisfy the uniqueness condition in Ref. [5]. Here O and P denote open and periodic boundary conditions, respectively. The symbol D denotes that the boundary condition depends on the model.

author	cell	dimension	parameters		uniqueness
			(a)	(b)	(c)
U. Brandt		$d \geq 2$	(t)	$\lambda_j = \lambda$ ($j = 1, 2, 3, 4$)	$(-\lambda^2)$ O ($d \geq 3$)
and A. Giesekeus		$d \geq 2$	$\frac{V}{t}$	$\lambda_j = \frac{1}{\sqrt{2}}$ ($j = 1, 2, 3, 4$), $\lambda_5 = \sqrt{2}\lambda$	-2λ O, P
A. Mielke	see text	$d \geq 1$	(t)	$\lambda_j = \lambda$	$(-\lambda^2)$ D
R. Strack		$d = 1$	$\frac{V}{t}$	$\lambda_1 = \lambda_2 = 1$, $\lambda_3 = \lambda i$, $\lambda_4 = -\lambda i$	λ O
		$d = 1$	$\frac{V}{t}$	$\lambda_1 = \lambda$, $\lambda_2 = -\lambda$, $\lambda_3 = 1$	$\frac{1}{\lambda}$ O
		$d = 2$	$\frac{V}{t}$	$\lambda_1 = \lambda$, $\lambda_2 = -\lambda$, $\lambda_3 = 1$	$\frac{1}{\lambda}$ O, P
H. Tasaki	d -sites	$d \geq 1$	λ_j	λ_j	λ_j D
H. Tasaki	d - and p -sites	$d \geq 1$	λ_j	λ_j	λ_j D
Model A		$d = 1$		$\lambda_1, \lambda_2, \lambda_3 = 1$	O, P
Model B		$d = 1$		$\lambda_1, \lambda_2, \lambda_3 = 1$	O
Model C		$d = 1$		$\lambda_j = 1$ ($j = 1, 2, 3, 4$), $\lambda_5 = \lambda$	O, P
